The Red Dog, which is located at the village of Red Dog, about one and one-half miles from You Bet, contains 140 acres. They are washing to bedrock through an 800-foot tunnel and a 160-foot shaft. The gravel in this claim is from 100 to 250 feet thick. The outlet to the Red Dog is Green Horn canon.

The Uncle Sam & Mallory adjoins the village of You Bet, but as yet it is not developed. This claim is thought by many to be the best one owned by the company.

The company owns two ditches; one with a capacity of 1,800 inches of water. It is 12 miles long and takes its water from Steep hollow. The other takes its water from the north fork of Green Horn, and has a capacity of 1,800 inches. The ditches carry their full capacity of water for six or seven months every year.

The Hayward claim, Dave Rose superintendent, is about three-fourths of a mile north east from You Bet. They are raising three streams of water, and are pushing work right along. Another claim will soon be opened by this company.

The Hussey claim, John Hussey, superintendent, is north of and adjoins the Hayward. This is also a good paying claim.

Taken as a whole, the prospects in this mining district are very flattering, not only for the present but for the next fifty years to come. The gravel is there and the gold is in it, and the boys will tug away until every particle will be gathered in.—*Dutch Flat Forum.*

Tellurium.

An immense excitement has lately broken out in this region, at Sacramento and elsewhere, over the report that tellurium in great quantities had been discovered on Rock creek, one-fourth of a mile this side of Union Mills, seven miles from this place and within a hundred yards of Bear river. Until this discovery was made, probably few of our readers ever heard of that strange mineral, of a silvery whitish color, so scarce and highly prized as hardly to admit of any commercial value being placed upon it. From the best information we are able to collect, this metal is used by manufacturers of fine cutlery to give the keenest edge to engraver's tools, surgical instruments, razors, etc., it being supposed that the famous Damascus swords were edged with it; and as an instance of its great value, we are told that a manufacturing firm in San Francisco bought a single pound for which the small sum of \$3,000 was paid. A small mine in Siberia, one in Hungary and another in Utah, are, we believe, the only sources from which this metal is at present obtained.

The discovery on Rock creek was made in a tunnel of the Bear River mining company, opened in their search for iron, and the mineral is supposed to be contained in the ore at the rate of six pounds or more to the ton—enough to make the mine of fabulous richness, should there be no mistake in the matter.

Numerous claims have been staked off, notices posted, and stock is already selling at a lively rate.

The lead has been traced upward to near the McCourtney place, where it crosses the river and appears on the Placer county side. Another organized company have staked off claims at this point, and will at once proceed to business.—*Wheatland Free Press.*

THE TEMESCAL TIN MINES.—There is a prospect of an early resumption of operations in the Temescal tin mines in San Bernardino county. These mines are situated about 24 miles southeast from the new settlement known as Pomona. During the past 10 years but little labor has been performed in these mines on account of a conflict in regard to the title. The property is reputed to be immensely valuable, and it is unfortunately that an industry of so much importance should languish on account of a wrangle over the right of possession. But it appears that the conflicting interests will soon be smoothly straightened out, and that a company of foreign capitalists will vigorously take hold of the work. The prospective operators are wealthy gentlemen from Amsterdam, who are engaged in importing tin from the United States on an extensive scale. The value of the tin annually imported by them is given at \$14,000,000. It is stated that they have bonded the Temescal tin mines from the various claimants to the amount of \$80,000, and that the money will be paid on the 1st of May next, and it is believed that the resumption of mining operations will greatly benefit business and property interest in that section.—*Los Angeles Land Journal.*

[PUBLISHERS' ANNOUNCEMENT.]

MINING AND SCIENTIFIC PRESS

For 1876.

THIS PUBLICATION, SO VALUABLE FOR MINERS, MECHANICS AND MANUFACTURERS,

Will enter upon its THIRTY SECOND Semi-Annual Volume on Saturday, January 1st, 1876. It has ever been and will still continue to be the aim and object of the publishers to make the PRESS

A Practical and Interesting Journal.

To this end, we aim, through the constant watchfulness of our editors and correspondents, to seize upon everything new in the way of mining and the various processes connected with the saving and separating of the precious metals, and place the same before our readers at the earliest day. It has been well said that

A Newspaper is a Window

Through which men look out upon all that is going on in the world. Our window is a special one, so placed and arranged as to bring within the scope of its vision all that is going on

In the World of Mining, Mechanics and Science.

Without a paper of this kind, the miner or mechanic is shut up in a small room or shop and can know but little of what is going on in the world around him in relation to his particular calling. In this age of rapid progress books are necessarily slow and behind the times. It is only through papers devoted to the specialty which he has chosen that one can be easily apprised of the discoveries and improvements which are constantly being made by his fellow workers, and without a knowledge of which he soon becomes a lag gard in the race.

The Value to the Community

Of such publication in disseminating important information, in checking useless and exploded experiments and in instigating important enterprises, can scarcely be overrated. Through them the readings and observations of thousands are collected and collated, and brought directly to the shop or table of the reader, without any effort of his own. For more trifling cost he is regularly furnished with an encyclopedia of just the information he needs—an unbound book forever issuing but never finished.

Nowhere in the Wide World

Is such an aid more needed than by the miner of California. It is needed alike in the mill, in the mine and in the placer. We have here

The Largest Mining Field on the Globe, Embracing a variety of minerals nowhere else found within the boundaries of a single field. We have here also, men gathered from every quarter of the globe bringing with them the collective wisdom of the world.

Useful, Practical and Directly from the Field

Of labor. The minuteness of books has been brushed away, and their minds are stored not only with the experience of the past, but also with the practice of the present. It is to this fact that we are indebted for our present

Able List of Correspondents,

Through whom we are able to promise to our readers so much that cannot be collected in the mere routine of office work. By the aid of such help our editors will be able, during the coming year, to do more than ever in furnishing information which shall be

Fresh, Novel and Interesting,

And which shall comprise all that is known of the latest and best means for saving gold and silver, and for economizing labor and cost in that direction.

Our Illustration Department

Will still continue to form an important feature, and no effort will be spared to make it of the greatest possible local and general interest to our readers. The important matter of

Home Manufactures and Inventions

Will also largely occupy the attention of the publishers and editors, and will be constantly encouraged, as an important means of furnishing employment to those who are seeking our shores, and adding to the wealth of the Pacific coast.

The Large and Increasing Circulation

Of a journal thus devoted exclusively to useful and practical information, speaks more in our behalf than anything we could say of ourselves, and is an encouragement to its further increase, especially in these times of trifling and trashy journalism.

The class of readers who are interested in such a publication as this, have no need to be anything more than merely reminded that such journals are necessarily more costly than the lighter class, such as are read by the "million" and thrown aside as soon as read. Considering the character and location of the MINING AND SCIENTIFIC PRESS, our rates are as favorable as can possibly be afforded and do justice to the great industries in aid of which we are laboring.

A Handy Map

Of California and the principal portion of Nevada will be furnished free to all subscribers who pay one year in advance, during the year 1876. The map is plain, printed on tinted paper, about 15x20 inches, showing townships in California, and the counties, railroads and principal towns in California and Nevada.

We Prepay the Postage

On all papers sent to subscribers in the United States. SUBSCRIPTION RATES, payable in advance: One year, \$4. Sample copies free to those who will assist in obtaining subscribers.

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water, supplied by pipe A, regulated under the oil by valve I, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rods and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; L, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v23

STEEL SHOES AND DIES

FOR QUARTZ MILLS.

Made by our improved process. After many years of patient research and experiment we have succeeded in producing STEEL SHOES AND DIES for QUARTZ MILLS.

which are unequalled for
Strength,

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially machinery for mechanical ore concentration, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mining line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

Rupture.

Use no more Metallic Trusses. No more suffering from Iron Hoops or Steel Springs. Dr. Rowe's Patent Elastic Truss is worn with ease and comfort night and day, and will and has performed radical cures when all others have failed. Reader, if you are ruptured try one of Dr. Rowe's comfortable elastic appliances; you will never regret it. ROWE ELASTIC TRUSS COMPANY, 609 Sacramento St., S. F.

(Continued from Page 133.)

to five or six feet in depth in the main drifts.

SURF TUNNEL.—The main header continues to be pushed forward at a very good rate of progress; material somewhat harder than last week. More quartz streaks are coming in, with a slight increase of water. Total length of tunnel, 1244 feet.

OSMOPOLIS.—Main tunnel north, following the vein, shows well in its face, being all in low grade ore with occasional rich streaks. The winze below that level is in good pay ore most of the way, and it seems to be widening it.

BELOCHER.—Daily yield, 450 tons of ore, keeping the mills on the Carson river running up to their full capacity. The shutting down of the mine a week ago and the stopping of the extraction of ore for a few days will make no difference in the yield of the mine for the month, as the mills had a plentiful supply of ore on hand. The grading for the new 400-horse power pumping engine is making good headway. Sinking the air shaft is going steadily ahead without hindrance of any kind whatever.

MORNING STAR.—Sinking the shaft is going rapidly forward. There is no water to contend with and the rock blasts out easy and works well.

WELLS-FARGO.—The east drift at the 500-ft level is now in 175 feet. It has been running in a strata of very hard porphyry of late, but it is getting softer, with indications of water.

MEXICAN.—The north drift on the 1465-ft level is being again advanced at a very fair rate of speed, the fact in quartz and ledge matter of a very favorable character.

GOULN & CURRY.—Repairing the shaft is nearly completed. Work on the lower levels will be resumed in a very short time.

KNICKERBOCKER.—The water is drained from the shaft, and work has been resumed on the lower levels.

ELY DISTRICT.

LOCAL MATTERS.—Pioche Record, Feb. 13: For the week commencing Sunday, the 6th inst., there has been shipped by Wells, Fargo & Co.'s express, bullion to the amount of \$51,251, which shows that Pioche is now doing the bulk of the bullion shipping and coming up in the old style. The pump on the Raymond & Ely mine has continued to work to the satisfaction of every one, the shaft being kept dry by about 17 hours working in 24, whilst sinking is steadily continued. We may at any time expect to record developments that will be of immense importance to Pioche, for as soon as the Raymond & Ely make a strike it will tend to place money in the other mines of Pioche to develop their resources. Taking the mining outlook throughout we think we can congratulate ourselves on being in a better condition financially than we have for two years past.

ALPS MINE.—During the past week from 15 to 16 tons of ore have been daily extracted, this ore being shipped to the Floral mill for reduction. The ore has worked well and given entire satisfaction to the superintendent. The mine shipped from the 17th to 27th of January \$17,294.

RAYMOND & ELY.—The pump of this mine is now working six, seven and sometimes eight strokes per minute, by which they manage to keep the shaft perfectly dry, running it about 17 hours out of 24. The progress of sinking is continued as rapidly as possible. On the eighth, ninth and tenth levels work is progressing. Ore which has heretofore pulped \$16, averages from \$135 to \$140. The constant increase of bullion and the large shipments of ore show the Raymond & Ely mine is a first-class one. If it was situated in Virginia City the stock would be rating at \$100 per share instead of \$22. However, it will not be long before a good strike will put it at large figures.

Oregon.

THE VIRTUE.—Oregon Sentinel, Supt. M. Hyde, of the Virtue mine, at Baker City, has shipped 436½ ounces of bullion, valued at \$9,000, to San Francisco, the result of 12 days' run with 20 stamps. This is the second shipment from this mine for the month of January, making a total of \$15,000 for this month. The new working shaft has reached a depth of 100 feet, and is being sunk at the rate of 15 feet per week. The vein of ore in the mine averages two feet. Between the first and second level north of the main tunnel, the ledges averages two feet, with a slope of 120 feet, and over 400 feet long solid ground. Here is found the richest rock ever found in Eastern Oregon.

CONNER CREEK.—Zelrock Democrat, Feb. 9: We are informed by Mr. S. B. McCord, who has just returned from Conner Creek, that the future prospects of that camp are looking up. Sleeper & Co. have added some new machinery to their quartz mill, and it was intended to start up this next week. White & Co. are now running their water quartz mill with five stamps, and will start their steam quartz mill, with 10 stamps, in a few days. From all the information Mr. McCord could obtain and observe, the White company ledge was in fine condition and prospects well in rich rock. He informs us that the miners there are in good spirits and expect a prosperous coming season.

THE MINES NEAR FORT LAKE.—Oregon Sentinel, Feb. 9: From parties who have visited the recently discovered placer mines in the neighborhood of Fort Lake, we learn that the mine is paying handsomely, and that a nugget of gold weighing some \$16 or \$17 was picked up one day last week. These mines were discovered in this wise: The water running through a rut which had been made by wagons bringing wood from that vicinity had washed the gold free from the earth, which was discovered by some parties who immediately took up the ground in that vicinity, and have been working at the same for the past few weeks. Some idea of their richness can be formed when we state that after washing up a piece of ground, not over eight or 10 feet in width and about 15 feet in length, \$200 was the result of the clean up. There have been some 20 acres taken up in that vicinity, but whether it will all prove as valuable as this, we have no means of knowing.

Utah.

LITTLE COTTONWOOD MINES.—Correspondence Salt Lake Tribune, Feb. 14: Since the beginning of the Centennial year we have been having snow in abundance. In the morning it is snowing, at noon it storms, and at night it is a regular juncane, that the bravest hesitate to face it. Old Sol seldom shows his smiling face, and a sight of him would now be a sure cure for sore eyes. The beautiful has accumulated to a depth of about 12 feet on the level. Business is dull, as may be expected, as it has been so long since the snow has melted, and the miners are compelled to do so through necessity. The trails to the mines are blocked most of the time and but little ore can be moved till the storm lets up. The ore haulers are having a rough deal this winter. The mines are still pounding away, and piling up plenty of good ore, so that when the road and trails are again passable, there will be a big lot of it rushed down the canon in a hurry.

MINERS are beginning to start from Virginia and vicinity for the Black hills, and several parties are making up to start early in the spring. Five faro sharps have also left from the same place to give the gold hunters a chance.

WHILE some men were working in the shaft of the Washington mine, near Hornitos, about thirty feet of earth suddenly gave way, and falling upon one of the workmen, named John Williams, killed him instantly.

A COLORED MEMBER of the Virginia House of Representatives has been expelled for abstracting money from the pay book of the Sergeant-at-Arms.

THE suspension of work in the Pennsylvania coal region throws about 60,000 men out of work. Over production is the cause. Work will be resumed March 11th.

THE temperance organizations at Buffalo have secured a fund of over \$10,000 to prosecute violators of the Sunday excise law. Thirteen prominent saloon keepers have been arrested.

"FOSTER" won the great four mile and repeat race for \$30,000 on Washington's birthday. The race was witnessed by 25,000 people. Time 7.38-7.53. The second horse was "Rutherford."

THE John Hopkins University in Baltimore, presided over by Professor Gilman, late of the California University at Berkeley, was opened February 22d, in the temporary buildings fitted up in that city.

THE Kern Valley bank, at Bakersfield, was robbed of \$27,000 on the night of the 18th inst. The bank manager, who was in the building, was knocked down and stupefied with chloroform.

A Times Paris dispatch it seems to me now decided that as soon as the Carlisle war is over Queen Isabella will enter Spain. King Alfonso will meet her at the frontier and conduct her to the capital.

RICHARD B. IRWIN, former agent of the Pacific Mail steamship company, has been arrested on complaint of Rufus Hatch, managing director, on the charge of having embezzled \$750,000, the property of the company. Irwin gave bail in \$50,000.

THE loss of life by the sinking of the steamer Strathside, in the English channel, in a collision with the steamer Franconia on the 17th inst., was frightful. Over 60 persons, it is said, went down with the vessels. Only a few of those on board were saved.

HENRY W. LONGFELLOW, Oliver Wendell Holmes, Ralph Waldo Emerson and 600 other professional and scientific gentlemen have petitioned Congress for the admission, duty free, of all books printed in other than the English, Latin and Greek languages.

A WASHINGTON dispatch says: In justice to Minister Schenck, the President will not accept his offer to resign until the investigation of the Emma mine scandal, ordered by the House, is concluded. It is now charged that among the parties who participated in the half million dollars expended in Washington, in connection with the Memphis-El Paso lobby years ago, were several present members of Congress and General Schenck.

ALL the material for the new water works at Virginia City is now on the way. The heaviest contracts have been let, and work on the mains will begin about May 1st, the present cold weather and frozen ground preventing work at present. Three large gradings have been made to accommodate the reservoir—one on the Ophir, another on Mount Davidson, on a line with Taylor street, and the third on the hill above the Ballou mine. All the piping and material ordered is of the best and most solid description, and purchased with a view to stand heavy pressure and the wear and tear of time.

THE reduction furnace of the North Almaden quicksilver company, which was leased by Captain J. H. Adams & Co. for the reduction of cinabar from the South Almaden claim, was started last Monday, and is now at work constantly.

PATENTS & INVENTIONS.**A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.**

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington D. C., Feb. 22d, 1876.

FOR WEEK ENDING FEBRUARY 8TH, 1876.*

SURGICAL BEDSTEAD.—Oliver Allen, Petaluma, Cal.

ELECTRO-MAGNETIC TRIPPING AND RECORDING MECHANISM.—Robert Bragg, S. F., Cal.

STIRRERS FOR ORE ROASTING FURNACES.—Jas. Brodie, S. F., Cal.

VEHICLE SPRINGS.—Eli Huntsington, Sacramento, Cal.

ICE MACHINE (four cases).—Samuel B. Martin, S. F., Cal.

HARVESTER.—Jas. F. Place, S. F., Cal.

APPARATUS FOR TREATING HIDES.—Charles L. Royer, S. F., Cal.

CONGREGATORS FOR ICE MACHINES.—David Smith, S. F., Cal.

HARVESTER.—Henry D. Willard, Vacaville, Cal.

REISSUE.

ALARM AND FARE REGISTERING MECHANISM.—Isaac Hyde, S. F., Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

ELECTRO-MAGNETIC POWER GENERATOR.—Robert Bragg, San Francisco. The object of this invention is to provide an arrangement by which sufficient power can be obtained from the action of an electro-magnet and its armature to perform certain stated duties. For the purpose of explanation, the arrangement and operation of the invention may be described with special reference to its application in fire engine houses, in which it can be used for the purposes of releasing the horses from their stalls, ringing bells, awakening the firemen, turning up the gas, opening doors, and for various other purposes, all of which can be accomplished by the electric current which transmits the alarm to the different engine houses, thus operating the various devices with which it is connected simultaneously. The wire of the fire alarm is connected with an electro-magnet, so that when an alarm is telegraphed the electric current will pass through the magnet and cause the armature to be drawn up against it. An upright trip bar, which is pivoted at its lower end, has a circular notch formed on one side of its upper end. A weight is arranged to slide up and down beside the trip bar, and this weight has a roller on one side, which can be caught on the notch in the trip bar when it is desired to suspend the weight and set the device. The armature has a shank which passes through a slot in a metal loop, which is secured to the edge of the bar opposite the magnet, and the end of the shank is headed on the inside of the loop. A spring serves to keep the armature drawn back away from the magnet. Now it is evident that when the electric current enters the magnet the armature will be drawn up against it, thus releasing the weight from the notch in the trip bar and allowing it to drop. This weight can be connected directly with the device to be operated, or it may be connected with and made to operate another trip bar, which will drop a heavier weight, in order to aggregate the power when necessary. The system of dropping weights is the subject of a former patent to the same inventor. Mr. Bragg also provides for registering the strokes of the armature, and as the strokes of the armature will correspond with the number of the box from which the alarm proceeds, the register will indicate that number properly. To do this he arranges a bar to slide vertically past the armature. This bar is operated by clock work, which is set in motion by the movement of the armature. To the shank of the armature is attached a pencil, which will mark across the passing rod each time the armature moves against the magnet, thus registering the number of the box, so that a mistake in counting the strokes of the alarm bell or gong can be rectified. In Mr. Bragg's former patents these tripping devices were operated by the hammer of the gong, but it is often desirable to have two or even more sources of power, so that each one can perform a specific duty. By the present arrangement he can employ any desired number of magnets and thus operate an equal number of separate weight powers, each one of which performs a separate duty. A spring could be used in place of the suspended weights, but its application would be substantially the same as for the weight.

IMPROVED FRACTURE BEDSTEAD.—Oliver Allen, Petaluma. This inventor provides a bedstead with all of the necessary appliances and conveniences for reducing and curing fractures of those bones in the human anatomy which require extension in order to keep the fractured parts in opposition while lesion is taking place. The bed is made with a solid bottom of boards, as such a bottom is better adapted to the various devices which are to be attached to the bed. A very complete and convenient combination of devices for reducing and curing fractures is provided. The parts of which the bed is composed can be readily taken apart, so as to permit of their being stowed in a small compass for transportation. The bed can thus be taken to the patient without trouble. By following the plan and employing the various devices described in the patent, fractures can be cured without shortening of the limb, while the patient is kept comparatively comfortable, and all his wants supplied without disturbing his position. If the bandage should become irksome its position can be shifted by securing a second bandage in another place and connecting it with the rear "stud" on the bed, which is made larger than the front one, to permit of the bandage being attached to it without interfering with the front stud. When this second bandage is perfectly adjusted the first one can be removed, thus changing the location of the bandage without disturbing the extension of the limb. A detailed description of this bed with its various devices would be imperfect without proper engravings to make it intelligible.

IMPROVEMENT IN HEADERS.—Henry D. Williams, Vacaville, Solano county. This improvement in headers for cutting grain consists in the use of a supplemental frame, carrying the elevator belt or draper, and so hinged or connected with the main frame that the two may be depressed for low grain without changing the level of the draper. It also consists in coupling the tongue to the main frame in a line with the axles, so that the driver has complete control of the machine, without being obliged to lift against the pushing of the team. All farmers are aware that with the usual style of headers, especially with the short frame and high wheels, there is always a great loss of grain when the straw is at all short, as the angle of the whole machine has to be so great in order to cut close to the ground that the grain is constantly rolling off the cutter bar and draper. With this machine that fault is remedied, while the inventor is still able to retain the advantages of the short frame and high wheels, because the frame is retained in a nearly level position, whatever may be the change in the angle of the main frame in depressing the front end and the cutters. By coupling the tongue in a line with the axles of the driving wheels the driver has complete control of the machine, without being obliged to lift against the pushing of the team, and the tongue is maintained at all times in a horizontal position, no matter how much the frame may be elevated or depressed.

ADJUSTING ATTACHMENT FOR HEADERS.—James F. Place, S. F. This improvement in headers consists of an attachment by which the inventor is enabled to retain the point of draft at the front of the machine and in a line with the pole, whatever change may be made in the elevation of the sickle bar and cutter for high or low grain. In the construction of headers which are driven by a team of horses attached to a pole projecting behind the header frame, this pole is usually hinged to the rear of the frame, either permanently or by means of adjustable plates. In the former case, whenever the cutters are depressed by raising the adjusting lever, an obtuse angle is formed between the pole and the header frame, thus making a sort of knee lever, against which the adjusting lever must be moved by a very great outlay of strength. If adjusting plates are used, it will be manifest that they would be practically useless in grain which varies in strength in different parts of the same field. In the construction patented by Mr. Place, he changes the fulcrum or point of support, about which the header frame works, from the rear to the front, and by this change the adjustment of the cutters for high or low grain is easily effected and without the outlay of much strength.

THE business of the Omaha smelting and refining works during 1875 was as follows:

Shipments of gold and silver.....	\$2,226,611
Shipments of lead.....	11,170 tons
Shipments of anti-friction metal.....	422 tons
Coke consumed.....	207 cars
Coal consumed.....	1,089 cars

There were received at the works during the year 1,277 cars of base bullion, (argenteiferous lead), 40 cars of ore, and four cars of soda. The number of men employed was 135, and the pay roll was over \$4,000,000.

THE Consolidated Virginia mining company has moved its assay office from the Savage assay office, which it has used since the fire, to its new building near its works.

SEVERAL abandoned gravel and quartz claims in Calaveras county are being reprospected with gratifying success.

RICH copper deposits have been discovered in Fresno county.

Mineral Land Patents.

Copp's Western Land Owner for February announces the following mineral patents issued during January:

California—Calaveras County—Joseph D. Royder, Royder placer; David B. Hughes, et al., Hughes & Son's Deep Gravel Mine; Alexander Queral, Paul Consolidated placer; John Jackson, et al., Union Shaft placer; Julius Bandmann, placer. El Dorado County—Anton Bentler, et al., Union Tunnel placer; Thomas Crushon, Plattaville placer; Joseph Immer, Brush Creek placer; Charles E. McLane, Dorsey & Bell, placers. Nevada County—Jacoo Arbogast, Rock Creek placer; William Rankin et al., Blue Bank Gravel Mine; Cold Spring and Blue Gravel Mining Company, Cold Spring and Blue Gravel Mine. Placer County—James L. Gould, Canon Creek Hydraulic and Blue Gravel Mine. Plumas County—Nicholas Gard, et al., placer. Yolo County—California Quicksilver Mining Company, Soda Spring.

Oregon—Royal Quicksilver Mine. Colorado—Boulder County—H. C. Brown, Forrest Lode. Park County—Charles Bamberg, German Lode.

Montana—Madison County—W. T. Harris, et al., placer.

Nevada—Storey County—Georgia Silver Mining Company, Washington Lode, Lyon County—Quinn Mining Company, Quinn Lode. Ormsby County—Athens Gold and Silver Mining Company, Athens Lode.

Oregon—Coos County—Simon K. Lane, et al., Pioneer Gold Placer.

Utah—Salt Lake County—Monroe Salisbury, Ohio River Mine.

OLIVE OIL.—One of our city dailies remarks that it may not be generally known that a considerable quantity of California olive oil is finding an appreciative market here, and is coming into quite general use in our hotels and restaurants. Samples of the oil were recently submitted by a prominent restaurant keeper to a party of his patrons, who were good judges of the article, for an opinion. After critically testing it, they unanimously reported it to be a first-class article, and were much astonished on being informed that it was of California production. The article is put up by parties at Los Angeles in cans and cases, and is sold here at a slight reduction from the rates of imported oil. Owing to the prejudice against home products, the agents have been obliged to label it Plagniol, a well known French brand.

JUMPERS.—The party of jumpers who took forcible possession of the Bunnel mine, near Bakersfield, last week, still remain in charge. They have constructed their dwelling at the mouth of the tunnel, erected fortifications of rock around it, challenge every man travelling that way, and allow no one to enter the premises. The report having been made that the party was moving over from the mine in disobedience to the injunction issued from the district court, steps have been taken to effect their arrest and commitment for contempt, but the overpowering force of about thirty men, armed with shotguns and revolvers, bids defiance to all adverse claimants and the authority of the officers of the law, and a row is expected if any attempt is made to eject them.

The shipments of coal from Seattle, Washington Territory, in January this year were 5,440 tons, against 1,933 tons in the same month of 1875.

The Ophir mine has already quite a town about it; the buildings now cover 10 acres of ground, and new structures are going up constantly.

ALFRED MURRISH, a miner at Dutch Flat, fell down the shaft of the Badger mine, a distance of 90 feet, Monday, and was instantly killed.

The Crown Point miners have presented Mrs. Jane Hill, whose husband was killed by a giant powder explosion a few weeks ago, with \$650.

BOTH the Savage and the Alta mines are to have heavy pumping machinery similar to that of the C. & C. shaft.

The ledge on the 340 ft level of the Lady Bryan mine on the Comstock, is 140 feet wide.

FIRST CLASS hoisting works are to be put up at the North Carson mine, on the Comstock.

RICH mines have been recently discovered near Swatee, Baker county, Oregon.

The Consolidated Virginia is at present employing 274 miners.

SANTA MONICA will have a planing mill.

THE STANLEY RULE AND LEVEL COMPANY, of New Britain, Conn., have reduced the prices of Bailey's Patent Adjustable Planes, both iron and wood. Send your address on a postal card and receive from them an illustrated circular of these and other superior tools.

Nothing racks the frame like a violent cough; yet nothing is more readily cured. It is only necessary to take HALE'S HONEY OF HOREHOUND AND TAR according to directions.

Pike's Toothache Drops cure in one minute.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

DEWEY & CO.

"Faith and Confidence"

LIVERMORE, Oct. 1st, 1875.

MESSRS. DEWEY & Co., Patent Solicitors: Gentlemen—Yours of the 29th ult. containing my patent to Elevated R. R. duly received, and I hereby return my sincere thanks to the MINING AND SCIENTIFIC PRESS Agency for your promptness and honesty in regard to our business connections. I have received a flood of circulars from Eastern firms, desiring to deal with me, but I have declined any communication with them and prefer, as soon as circumstances will permit, to negotiate with and patronize a home institution; one in which I have faith and confidence—DEWEY & Co. Again thanking you for your promptness in securing my patent, I remain, obediently yours,

WM. H. HARRISON.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.

R. W. CROWLEY—California.

JOHN ROSTROFF—California.

G. W. McGREW—Santa Clara county.

J. M. McANTRUM—Los Angeles, Santa Barbara, Ventura, San Bernardino and San Diego counties.

J. W. RILEY—San Francisco.

APPEALATION ABROAD.—We copy the following from the *Mining and Monetary Gazette*, of London, Eng.: "We deemed it advisable, as affording valuable information to our readers, to publish in recent issues of *The Gazette*, the full text of the 'United States Mining Laws and Instructions, by the Commissioner of General Land Office,' taken from our talented contemporary, *The Mining and Scientific Press*, of San Francisco. The documents have now been issued in a handsomely bound volume by Messrs. Dewey & Co., the publishers of our transatlantic contemporary, and it will be found very useful to those already interested in American mines, and to others who may be tempted to embark in that enterprise in the States."

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

California Acclimatizing Society—Loca-

tion of principal place of business, San Francisco, Cal. Notice is hereby given, that at a meeting of the Board of Directors, held on the fifth day of February, 1876, an assessment of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary, at the office of the company, room No. 37, Nevada block, northwest corner of Pine and Montgomery streets, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the fourteenth day of March, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the third day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. W. W. TRAYLOR, Secretary, pro tem. Office, room 37, Nevada block, San Francisco, Cal.

Eureka Stone Manufacturing Company—

Location of principal place of business, San Francisco, California.

Notice is hereby given, that at a meeting of the Board of Directors of said company, held on the twenty-sixth day of January, 1876, an assessment (No. 3) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 567 Market street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the first day of March, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the twenty-second day of March, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. C. D. MOWELL, Secretary.

Office, No. 567 Market street, San Francisco, Cal.

Josephine Gravel Mining Company—

Principal place of business, San Francisco, Cal. Location of works, Brushy Canyon, Placer county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-third day of February, 1876, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold and silver coin, to the Secretary, at the office of the company, 431 California street, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the tenth day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. WM. SMALL, Secretary.

Office, No. 531 California street, San Francisco, Cal.

Mariposa Land and Mining Company of

California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa county, Cal.

Notice is hereby given that at a meeting of the Board of Directors, held on the twenty-third day of February, 1876, an assessment (No. 4) of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States currency to the Secretary, at the office of the company, room 35, Nevada block, No. 299 Montgomery street San Francisco, Cal. or to the Assistant Secretary, at the office, No. 9 Nassau street, New York, N. Y.

Any stock upon which this assessment shall remain unpaid on the twenty-fourth day of March, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before will be sold on Monday, the tenth day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEONARD L. FAY, Secretary.

Office, room 35, Nevada block, No. 299 Montgomery street, San Francisco, Cal.

Moore's Flat Blue Gravel Mining Com-

pany. Location of principal place of business, San Francisco, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment levied on the twentieth day of December, 1875, the several amounts set opposite the names of the respective shareholders, as follows:

Carelessness.

It has become so very common to hear of accidents from the reckless use of firearms, that it is but fair to conclude from their great increase in numbers, that either we are growing more careless or else guns are more plentiful. While there can be no doubt that the latter, when accompanied by the low price and poor quality of the article, has much to do with it, yet it does not excuse the many accidents which happen through worse than carelessness, and for which the usual plea is, "I didn't know it was loaded." It has several times been proposed to make it a criminal offense to point a gun (loaded or not,) at another. This would be of very little use in making us more careful, for in most cases the offense occurs when it would not be punished. Under the head of "making excuses," the *Scientific American* uses this somewhat harsh, but nevertheless true language:

"Our statute and other laws distinguish between murder committed with premeditation and malice, from that committed without forethought. The insane escape punishment for crime, however heinous. The man who shoots his sister by accident is at once acquitted. But does the bullet discharged by accident prove less fatal than it would had murder been intended? The severed artery, the pierced lung, the congested brain, listen to no excuses. To him that is murdered it is all one whether it was premeditated or not."

The American Workingman.

The following is an extract from the first speech delivered in Congress by Hon. D. J. Morrell, President of the Cambria iron company. It has the true ring:

The American workingman must live in a house, not a hut; he must wear decent clothes, and eat wholesome and nourishing food. He is an integral part of the municipality, the State and the nation; subject to no fetters of class or caste; neither pauper, nor peasant, nor serf, but a free American citizen. He has the ballot, and if it were possible it would be dangerous to degrade him. The country stands pledged to give him education, political power, and a higher form of life than foreign nations accord their laborers, and he must be sustained by higher rates of wages than those of Europe. Our industries operated by American citizens must be freed from foreign interference and organized into a distinct American system, which will exact some temporary sacrifices, but result in general prosperity and true national independence. In maintaining diversified industries we utilize every talent, provide a field for every capacity, and bind together the whole people in mutual dependence and support, assuring the strength and security of our republic.

LOWER CALIFORNIA MINES.—The mines of Lower California are very rich, although but little is generally known concerning the wealth of that section of the country. The mountains which contain such inexhaustible sources of wealth are supposed to be a continuation of the same ranges as that of the Sierra Nevada. Most of the miners of Lower California are Mexicans. The ore is conveyed from the mines to the mills on pack mules, a distance of from 10 to 12 miles. The bullion is shipped to La Paz by wagon, and thence by schooner to San Francisco. There is a large number of mines in that section which could be worked with profit, but, through the arbitrary measures of the Mexican government, but little in the way of developing is accomplished. The country is suffering for lack of American brains and capital. With mineral resources unsurpassed, inexhaustible beds of salt, immense deposits of guano, a fine climate, to say nothing of its proximity to the Gulf of California, where almost every description of fish is abundant, the country is permitted to remain in an unproductive state year after year, and our people know almost as little about it as they do about the central deserts of Africa. Enterprising merchants and farmers would find a splendid field there for the exercise of their genius and energy, and it is hoped that the day is not far distant that will witness the annexation of Mexico to the American Union.

MENDING RUBBER BOOTS.—A great many directions have been published for mending india rubber boots and shoes, most of which were worthless. The *Scientific American* says that the following can be relied on: Procure a small tin box of prepared india rubber in a semi liquid condition, which can be purchased for a few cents at almost any store where india rubber goods are kept for sale. The boot must be washed clean and dried. Then the surface around the rent is to be roughened a little with the point of a knife, after which the semi-liquid rubber is spread on with a spoon as thickly as it could be without flowing away. Then a neat patch is prepared and covered with one or two coats of rubber. When the prepared rubber is almost dry, the patch is applied and held on firmly for a few minutes.

INTELLIGENCE has just reached us that a rich and extensive strike has been made in the third level of the Paymaster mine, at Ward district. We understand that it is the first ore found in that particular locality of the mine.—*White Pine News.*

VERY severe weather has been experienced in the Cassiar gold fields. Mules suffered terribly, owing to lack of fodder, and had to be fed on bread to sustain life.

The HARRISON Burr Stone MILLS. \$1000 CASH Offered for their EQUAL. Will grind any thing. Send stamp for new Illustrated Catalogue. Just issued.

PRICES
60 percent less than any other mill in market.
540 bush. corn ground in 10 hours in 150 mill weight 300 lbs.
Manufactured by Harrison Burr Stone Mills, Ct.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30 in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

SAN FRANCISCO
Pioneer Screen Works,
Removed to 32 Fremont Street, near Market.

J. W. QUICK.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price \$2.50 coin, or \$3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurates, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book; by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 175 pages. Price, \$2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked; with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M. D. 1867; cloth bound, 114 pages. Printed and sold by Dewey & Co. Price, \$1; postage free. The best written work, and most complete work on the subject treated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by DEWEY & Co., Mining and Scientific Press Office, S. F.

Mining and Scientific Press,

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for the best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi. As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Minors, Assayers, Millman, and Metallurgist in the United States should take it.

Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

UNITED STATES

Mineral Land Laws, Revised Statutes,
And Instructions and Forms Under the Same.

We have just issued a pamphlet containing the general mineral land laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Register's Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Change of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of MINING AND SCIENTIFIC PRESS, S. F.

Number 10.

The Bonanza Mines.

The Comstock lode still continues unremittingly to pour forth its treasure. The Consolidated Virginia mine yielded for the month of February, up to the 23d ult., \$1,700,001.95, an excess of \$746,000 over the yield of the previous month for the same time. The close of the fiscal month occurs on the fifth of each month, so the yield will not fall short of \$3,000,000 for the month of February. The Occident mill, which was unavailable for crushing in the early part of the winter, began crushing ore from this mine last week. The California stamp mill is crushing its 300 tons of ore per day, while the pan mill is working with the utmost perfection. Sluices for carrying the slimes to the old Gould & Curry reservoirs, in Six-mile canon, have been erected, so that nothing whatever shall be lost. The mine paid its usual dividend of \$10 per share last month, equal in the aggregate to \$1,080,000.

In the California mine work is going ahead successfully with rich ore on all hands. The mine is expected to announce \$3 dividends in May. The north drift of the mine on the 1550-foot level is steadily advancing to the northward, the face still in ore of a very rich character. The winze being sunk in cross-cut No. 6 on the 1500 foot level, to connect with this north drift, is down 28 feet, the bottom also in very rich ore. Work has been resumed in the main north drift on the 1500-foot level, that drift having been stopped since the conflagration last October; it will now be pushed ahead until it connects with the Ophir mine on the level. As soon as this connection is made, and ventilation obtained, cross-cutting and developing that portion of the mine will be resumed. Sinking the C. & C. shaft is going steadily ahead.

The Belcher ore breasts are yielding finely, especially those opened on the new ore body on the 1200-foot level. The yield is 450 tons of ore per day. The Gold Hill News says the mills are all kept steadily running, and the ore proving rich in gold, the average value of the bullion being over two-thirds gold to one-third silver. The bottom of the winze being sunk from the 1500-foot level downward, is developing better ore than was expected, and the prospects of that portion of the mine are growing daily better for the development of a fine body of paying ore. The grading for the new and powerful pumping machinery at the air shaft will be completed in five or six days more, when laying the foundations will be commenced.

The Ophir is yielding 200 tons of ore per day, and the ore breasts are looking and yielding finely. Three mills are now running on ore from this mine. The new ore discovery in the face of the east drift on the 1600-foot level, north of the old workings, is opening up splendidly, and promises a very important development. The upraise in the east ore body from the 1300-foot level, running to connect with the east drift on the 1100-foot level for air purposes, is in rich ore. This is also a very important feature, as this ore lies nearly 500 feet east of the shaft, and entirely east of all the former prospecting done in that portion of the mine.

The latest report from the Fort Lane diggings in Jackson county, Oregon, are more conclusive as to their richness than ever. James McDougal, a miner engaged in ground sluicing there, took out a nugget the other day worth \$400, and several other very valuable specimens have been found. The only drawback to working the mines at present is the scarcity of water; but arrangements are being made to obviate this difficulty.

A MINER in the Silver Hill mine fell down a shaft, a distance of 110 feet, the other day, but though somewhat bruised and cut about the head, he worked out the remainder of his shift before having his wounds dressed, and is now all right again.

The railroad troubles in Santa Cruz county have been compromised, and the narrow gauge is to pass through Watsonville, which it was designed to leave at one side.

The Bigelow Engine.

We give herewith an illustration of the Bigelow portable engine, which is in use extensively in the Eastern States, but which is now introduced on this coast for the first time. Messrs. Neylan & Young, 18 and 20 Spear street, agents, expect the first engine of this class to arrive in a few days. It is claimed to be the cheapest portable engine on the market, and is made in sizes from four to 15 horse-power. Bigelow

engine and boiler is furnished a cast iron base and smoke bonnet; Judson's patent governor; pump; steam gauge; glass water gauge; three try cocks; safety, stop and check valves; blow off cock; steam, exhaust and feed water pipes; chain and air cocks; one set of grate bars; in fact, everything complete, ready for running, except the smoke stack.

The boilers are made after the most approved plan, from Pennsylvania charcoal, No. 1, and best flange iron. The tubes on the boilers are first-class. A great many of these engines are in use in the Southern States, where they are great favorites. As before stated, the specialty

THE BIGELOW PORTABLE ENGINE AND BOILER.

& Co., of New Haven, Conn., the manufacturers, who have been makers of boilers and engines for many years, say that they were, by many inquiries for a low-priced portable engine, led to see if they could not reduce the cost, and were surprised at the amount of the cost of the bright and finished work on these engines, where, for all practical purposes, paint was just as good.

This led them to produce and offer to the public an engine of perfect workmanship, but one in which customers were not compelled to pay for bright and finished work when they did not want it. The Bigelow portable engines are made in large quantities, fifty at a time, and by proper tools and machinery, the manufacturers were enabled to systematize their work and produce a good engine for a low price. They use a cast steel connecting rod and metallic piston rings. With each combined

claimed for this engine by the manufacturers is that it is not only cheap but good.

The Livermore coal mining company have lately taken steps to secure the right of way for a railroad from their mine to Livermore, to connect with the Central Pacific, whereby cars loaded with coal may be transported direct to Oakland, San Francisco and San Jose without unloading.

The Virginia Enterprise says: "There are many more workmen in this town than can find work. All of our benevolent societies are taxed to their utmost to afford assistance to men who have arrived here without money."

A survey is soon to be made for a new wagon road to connect Downieville and Nevada City.

"STOVE-LID CURRENCY" is the name for trade dollars in Eureka.

The Fryer Process.

Although the details of operation of the Fryer process are as yet unknown to the general public, and there is considerable grumbling that the secret should be kept so long, there is still great interest manifested in it. Criticisms, both adverse and favorable, are freely indulged in, of course, but any authentic decision must be delayed until the *modus operandi* is known. The proprietors naturally do not expect the mining community to pronounce favorably upon any process which they do not understand and which they are not permitted to see tested practically. Although the Fryer works at Grass Valley have been in operation for some time, and many samples of rock from different localities have been tested to the satisfaction of the parties interested, it is no proof to those who only know these matters by hearsay, that success has been attained.

We, in common with the mining community, are somewhat impatient that the veil should be lifted, although we are assured that the delay will inure to the benefit of the mining interest. We are authorized to state that at no distant day the works will be opened for inspection, and a number of the representatives of the press and mining men will be invited to attend and examine the works and method of operation. We shall, as soon as possible, give illustrations of the machinery in use, and a description of the whole process. We are informed, on good authority, that in the delay that has occurred, while the process has not been changed in any principle and work has not been stopped, many important improvements have been inaugurated, having in view the saving of time and money. The works are now running day and night. Mr. Fryer is aiming at perfection in his process, and is certain that it can be manipulated as cheap as any first-class mill in the State, running by steam power. Like the mill system it is continuous. We shall keep our readers duly posted on anything which may occur of interest on this subject.

Since the above was in type we have received a communication from Mr. Fryer, which we give in another column. It will repay perusal. In his letter, Mr. Fryer asks every one to withhold criticism until after the whole case is made public.

"CRAWLING GROUND."—The Calaveras Chronicle says: Operations are being prosecuted with indomitable energy in Veith's gigantic hydraulic in Tunnel ridge. For some time past work has been confined to running off top dirt, the whole hill, for several hundred yards back from the face of the claim, comprising four or five acres, having slid in. From the surface down to a depth varying from 20 to 50 feet, the soil is a mixture of gravel and clay, resting on a hard pan underneath. The heavy rains of the winter, together with the hydraulic operations at the base of the ridge, have loosened the surface, and it is gradually gravitating towards the gulch below, slipping over its solid gravel foundation. The surface is thickly studded with tress, which the sliding process has tilted into every possible position except the perpendicular. In fact, the whole thing looks like the debris of an Alpine avalanche. We are informed that the hill frequently "crawls" 12 feet during the night, and that it has required incessant labor and the employment of several powerful hydraulics to prevent the burying of the mine altogether. Not much further trouble from the slide is apprehended, however, and an opportunity for piping out the bottom and "cleaning up," will soon be afforded.

JOHN DIX, who for the past two years has been working what is known as the Dayton claim, about two miles above the forks of Butte creek, picked up a nugget last week weighing 48½ ounces, and valued at between \$800 and \$900.

The production of gulch gold on Aod below Spanish Bar, Clear Creek county, Colorado, amounted to \$80,000 last year, showing an increase of over \$30,000 on the figures of 1874. Ten claims were worked, two of which were exceptionally rich.

MISCELLANEOUS.

Thoughts on "The Mission of the Press."

[From Pacific Rural Press.]

Editors Press:—When the rain pours day and night for weeks, days and hours, daily existence becomes monotonous. We have read and reread the last few numbers of the *Rural*, the *Call*, and our county contributions to current literature, until our head seems full of notions, worse and more confounded than a Yankee curiosity shop.

From reading we take the pen; from receiving the thoughts of others we feel as if we should also give out thoughts, so as to be a giver as well as a receiver. A thought born of the mind is buried there, except we give that thought entrance in some shape. When recorded by the pen, that thought becomes a fact, but when it has been transcribed by the printing press it almost becomes immortal, and goes out to fulfill a mission either for good or evil. Many a thought finds a prominent place in the world's record book which the writer would fain recall; but once on its mission no regret can wash out the stain. This reflection sometimes may withhold thoughts which otherwise might find expression, making us careful that no heart will be saddened by their effects, no eyes dimmed by being uncharitable, no pathway pointed out wherein the unwary might go astray, no desire to expose the frail side of human experience, but a wish to instruct and elevate, to cultivate Hope and Charity—white-winged angels of peace and purity.

Too often the daily press of cities panders to a depraved appetite, exposing the weak side of human nature, sinking still deeper the victim of fate into the maelstrom of hopeless despair. Suppose, for effect, that the city press should stay the recital of society's noisier sores, even for one day, and herald forth all the good apparent in human life and action. The rebound would convulse social life and private gossip. But how much better would it be for the peace and innocence of the inexperienced if these filthy details of every day weaknesses were altogether suppressed, and only the good deeds of men and maidens made public. The mind grows on what it feeds upon, and these scandal dishes served up by the public's great oracle—the press—keeps society in the van of all that depraves human nature.

It is a relief to turn to the Home Circle of the *Rural*, where morality, practical religion and virtue stand pre-eminent. Rural life is displayed in its simplest, holiest guise, health ennobled by strict temperance, and a walk with nature and divine laws; making work, worship and enjoyment, praise.

This Centennial year should inaugurate a higher standard of literature among the so powerfully influential daily papers of the metropolis; covering up with a mantle of charity the faults and failings of "brothers and sisters," and holding up for emulation the good deeds of the good Samaritan, or even those accounted as sinners. The reading mind would not then be polluted by exaggerated closets skeletons, or the actions of weak mortal nature.

Messrs. Editors, you will excuse my lengthy remarks on this all important theme; but if every reader had the same unsatisfactory reflections as myself after reading the pages of our public dallies, the necessity for such a scandal dish would soon pass away. How glad we feel at the recital of some noble act; some deed of heroic valor; some sentiment appealing to the better and higher instincts of the soul. If this teaching were more universally practiced how soon would the evils complained of pass away, and a spirit of emulation be cultivated for a higher good? We would allow the stricken and the sinning to suffer in secret without the anguish of knowing that thousands of readers were gloating over a magnified dish of the heart's burden, crushing many good and noble natures into the grave of the envious. May a warm fraternal and paternal spirit animate the pen of the votaries of the press, is the desire of yours in transitu.

JOHN TAYLOR.

Mount Pleasant, Feb. 11th, 1876.

Jersey Mining District.

A correspondent of the *Silver State* says: The Jersey mines are situated about 60 miles south of Winnemucca, with a good natural road the whole distance, and good feed and water the entire route, and if your townspeople make half the effort that ought to be made for the trade, nothing can keep Winnemucca from controlling it. It is the county seat, and as a natural consequence, communication will be established by mail between the two places; but Battle Mountain is making a big effort to command the prize. Fortunately the hill passed for the division of this county three years ago did not include this district.

The Jersey mine was discovered in May, 1874, by the present foreman, Land Tremble, and has paid its way ever since, and shows that prospecting will pay if followed up, as at the time of its discovery Tremble was heavily in debt, and at the time of its sale to the present company he was as much ahead. Since the sale, 30 days ago, the company have built

a furnace with a capacity of 45 tons per day; cut a grade from the furnace to the mine, three-fourths of a mile long, at big expense; built offices, laid out a town, sold a great many lots at prices ranging from \$100 to \$500, burnt coal, bought and paid for eight large teams, and have engaged all the hay and grain in Pleasant valley at liberal prices. The mine is at the present time prospecting to a considerable extent. The north tunnel is in a depth of 300 feet; the south tunnel a distance of 80 feet; the incline is down from the tunnel level 100 feet, and from the surface to the bottom of the shaft the distance is 300 feet. The ledge is from two to 12 feet wide, and at no place are there any barren spots, so far as yet prospected. J. Sevenoake is superintendent of the works, and a more persevering, energetic man cannot be found on the coast to-day.

White Pine Mines.

The White Pine News of the 19th says: We are indebted to Deputy Assessor Comins for the following information in regard to the product of the mines of White Pine county during the last four years, as taken from the Assessor's books:

Quarters Ending	
March 31, 1872.....	\$234,439 33
June 30, 1872.....	133,454 47
September 30, 1872.....	261,806 00
December 31, 1872.....	108,798 28
Total for 1872.....	\$738,498 08

Quarters Ending	
March 31, 1873.....	\$ 38,425 35
June 30, 1873.....	178,832 09
September 30, 1873.....	165,737 00
December 31, 1873.....	112,802 50
Total for 1873.....	\$495,796 95

Quarters Ending	
March 31, 1874.....	\$ 49,688 77
June 30, 1874.....	124,137 10
September 30, 1874.....	203,013 79
December 31, 1874.....	223,001 97
Total for 1874.....	\$599,841 63

Quarters Ending	
March 31, 1875.....	\$ 96,690 25
June 30, 1875.....	284,876 77
September 30, 1875.....	218,304 40
December 31, 1875.....	265,968 54
Total for 1875.....	\$865,839 96

The Eberhardt & Aurora company's mines produce the largest amount of ore, and for two years, 1873-4, these mines were lying idle, which accounts in a great measure for the smallness of the returns during these years. In 1875 their mill only ran nine months. From present indications, we judge that the yield this year will double any for the past four years. The outlook for this county was never more promising than at the present time. However, for a camp that attracts no more attention than this, \$2,697,026.52, in four years, is not bad.

An Expert's Estimate of the Bonanza.

The following letter was written to one of the leading stock operators by Robert Barton, a mining expert of great ability and experience:

DEAR SIR:—We arrived here on the morning of the 2d, and aside from my business, are having a very pleasant time. My visit through the Consolidated Virginia and California yesterday and to-day has been most interesting and satisfactory, for Mr. Fair seems to exert himself to have me see everything of interest in these two mines. He has done marvels in the way of reconstructing such elegant and substantial works in so short a time since the fire, and you cannot give him any too much credit for this and the skill and good judgment displayed in the development of these two mines. As far as Consolidated Virginia and California are concerned, of course I look for big showings, but I find the 1500 and 1550 levels—"and especially the latter"—simply marvelous in quality and quantity of the ore. That Consolidated Virginia alone can be made to produce 1000 tons of ore a day for at least five years to come, counting on nothing not yet developed below the 1700 level, there cannot be the least doubt; and this ore will mill at an average of about \$150 per ton for all the ore in eight above the 1500 level, and from that up to \$300 per ton for all the ore between the 1500 and 1700 levels. The 1550 level is opening up a perfect sea of the richest kind of ore, but I think the next 100 feet deeper will beat even this, for no doubt the full width or rounding of the ore body will be about the depth of 1600 feet, and right here let me state that I would give the Consolidated Virginia company \$400 per ton of ore for a picked section below the 1550 level, say 200 feet long, 100 feet deep and 60 feet wide, making close on to \$40,000,000 for the section, and at that my chances would be good in pocketing as much myself. I would also say that very few people probably realize the immensity of this mountain of ore, taking only what is in sight in Consolidated Virginia alone, when you tell them that it is not less than 400 feet in length, 300 feet in depth and 250 feet in width, saying nothing of what is in perspective in the South Consolidated Virginia ground "yet undeveloped," and below the 1700-foot level. It would be about the size of one of our San Francisco six 50-vara blocks, standing up in the air 300 feet high. Thus you can readily see that the ore so far worked out of Consolidated Virginia below the 1400-foot level has made but a small impression on this block of ore, and the section above referred to at \$40,000,000, "though perhaps the cream of the ore body,"

would make but a small hole in such a large mass. As far as Consolidated Virginia and California are at present developed I cannot see any material difference in their values. But whatever it may prove to be I am confident Consolidated Virginia will have the best of it in depth, having my own reasons to think that the ore will work its way south, but of course this is a matter of conjecture. On close inspection into adjoining ground, I should be able to express a decided opinion as to its prospects; but remembering quite well the old developments of the North Potosi, during Bonner's time at the Gould & Curry and Savage, I think an ore body should exist in the North Savage and South Gould & Curry, and possibly this body of water just tapped may lead to something of this kind. Savage ought at once to have similar pumping machinery to that of the C. & C. shaft, and it ought not to take over sixty days to place it ready for work.

I have no desire to look into the other mines here at present after what I have just seen, and if you come across any wise and doubting Thomases who cannot see it in this light, I am sure they can look for themselves, which is the next best thing. I will promise them the greatest treat they ever had. Respectfully,

ROBERT BARTON.

Virginia, Nov., Feb. 4th, 1876.

A Bird Hatched out from an Artificial Egg [?]

The *Allgemeine Zeitung* makes the announcement that Prof. Geifling, of Brunsberg, Germany, a gentleman somewhat known to the scientific world as a clever chemist, has of late been turning his attention to the artificial production of the egg, and after innumerable experiments, during a period of ten years, he succeeded in the mysterious combination of the elements so as to form a compound similar to the natural article.

Encouraged by this success, the doctor set about his almost hopeless task with a determination to surmount every obstacle. He felt satisfied that it was only by means of galvanism that his object could be accomplished, and of a battery of constant, equal and moderate power.

After trying various kinds of batteries he by accident learned that a constant battery of moderate power had been constructed in England by placing a plate of zinc and a plate of copper in an ordinary flower pot, and keeping the earth moistened with ammonia.

He immediately constructed such a one, and after various modifications, succeeded in adapting it to his purpose; and had the satisfaction of seeing his labor crowned with success, and reducing from elements a substance similar in all respects to an egg.

Now came the exciting period of his labors, to see whether this artificially formed egg could be hatched by heat. He placed it in his hatching oven, and watched it through a glass door almost constantly, scarcely taking time to eat or sleep, until he had seen the success of his grand experiment.

Day after day he watched with patient assiduity the consummation of his darling scheme, and at last had the satisfaction of witnessing the consummation of his hopes. On the 20th day, a small hole was observed in one side of it, and shortly after the bill of a bird was thrust through, and next morning he had the satisfaction of finding in the receiver a live bird, of some unknown species, perfect in its anatomy, but, strange to say, entirely without feathers!

"This most astonishing result," remarks the paper from which we quote, "has almost upset our previous notions of natural philosophy and the governing laws of animal organism. As we gaze upon the featherless bird hopping about and feeding upon the seeds given it, we begin to doubt the reality of our own existence, or that of anything about us!"

"The professor, urged on by his success, has set about another analysis, and has no doubt of being able to produce perfect birds of every known species."

The *Allgemeine Zeitung* of the next day remarks that the whole city is electrified with the development. A very pretty hoax, which will no doubt deceive many for the time being.

WESTERN HUMBOLDT.—A correspondent of the *Silver State*, writing from Rye Patch, says: The sunshine of prosperity is again beginning to illuminate the visage of "ye honest miner," and this locality is filled with never tiring prospectors, whose countenances indicate the near approach of good times. The welcome hum of bustling industry is again to resound through the "hills of the Montezumas," and old Humboldt is preparing to take its place in the front rank of mineral producing counties. From every canon where the pick and drill are busy, good results are shown. The Rye Patch mine is looking better than ever before. The capacity of the mill will be increased, and the rattle of the stamps will sing in harmony with the rattle of the dollars it produces. Relief district will arouse from its sleep and play its part in forcing the "ragged edge currency" to the wall. The Oreana smelting works will puff and roar as it did before, and add its meter to the crest of the silver wave. In San Jacinto district the developments are flattering, and the ledges of chlorides and galena ores are as huge as the whisky rings of the incorruptibles. The copper mines of the east range are attracting considerable attention, and experts and their eye glasses are constantly occupied in searching nature's matrix for silver lining to their purses.

The Black Hills.

The Black hills mining excitement still continues, and is even on the increase as spring draws near. Parties of miners are leaving for the hills from all quarters. Among the people who are organizing mining expeditions into the interior are many substantial, well to do people in Iowa, Dakota and elsewhere, who are doing well enough on their lands, but who cannot resist the impulse to go further and seek a short road to fortune in the new gold fields. There are, as is usual in all such cases, large squads of roughs who are doing considerable personal damage among themselves as well as among the trains of people whose intentions are good. There is a crowd of thieves and murderers out in the hills who have been swinging their revolvers around pretty recklessly, and these the Marshal has been making the necessary arrangements to capture. A party of 157 men left Yankton last week for the hills, and over 100 miners left Sidney, Nebraska.

Advices by mail from Red Cloud, in the Black hills, from official sources, state that there is no truth in the report that Red Cloud intends to leave the agency with a part of his tribe, for the northern country, to fight the Crows. Neither is there any truth in the report of a fight among the Sioux about the white people going into the Black hills. The state of affairs at the agency remains, as it has for the past year, quiet. Retractions are being issued regularly, and there is no prospect of the slightest opposition on the part of the Indians to the occupation of the Black hills. On the contrary, other reports say the Indians will prevent any occupation of their reservations by miners. If the miners go there in violation of the Indian treaty it is hardly to be expected that the Government will protect them, and they will have to fight it out themselves.

Custer City and Hill City both have a population already of some 600 souls. Several other towns are growing up, and if gold is found in abundance, it is anticipated that, in spite of the absence of Government protection, there will be a pretty considerable rush to the hills in the spring. One man came to Chicago a week ago to purchase a sawmill, which he has taken out to that region, and as an indication of the prospects of a large emigration, it may be mentioned that a new stage line is about to start from Yankton to the Black hills.

Although we are not among those to advise miners here to go to the Black hills on any "wild goose chase," there are many who have no doubt made up their minds to go, and to them the following information, derived from Hon. J. H. Burdick, U. S. Marshal of Dakota Territory, by the Chicago *Inter-Ocean*, will be of interest:

The Dakota Southern railroad company, through their general superintendent, answer some inquiries in regard to the route of travel and rates of fare, which may be of some interest to parties contemplating a trip to that section. The Pierre route, says the superintendent, will be the choice of all. The first boat leaves Yankton, via this route, on April 10th. The fare from Yankton to Fort Pierre by boat is \$5, including berths in the state room, while meals are 40 cents extra. The stage fare from Fort Pierre to the hills is \$12.50, the distance being 100 miles, and the time occupied 24 hours; the time from Yankton to Fort Pierre is 36 hours by boat. These rates include 50 pounds of baggage to each passenger. Adding the railroad fare from Chicago to Yankton—\$17—this makes the cost of going to the Black hills from Chicago just \$34.50, and by this line there will be only 100 miles of staging.

A Cheyenne paper gives the distances from that place to Custer City, on French creek, in the Black hills, as follows, by the route taken by General Custer last summer, the shortest yet made.

	Miles.
Cheyenne to Fort Laramie.....	93
Fort Laramie to Rawhide.....	18
Rawhide to Running Water.....	24
Running Water to Old Woman's Fork.....	12
Down C. W. F. to Sage creek.....	24
Thence by right road to Cheyenne river.....	26
Cheyenne river to Custer City, via ridge road and Ruby Springs.....	49

Total distance.....	236
Custer City to Spring creek.....	8
Down Spring creek to Camp Crook or Stand-off Bar.....	10
Stand-off Bar to Rapid creek.....	12
Rapid creek to Box Elder.....	15

Aggregate.....280

The route to the gold fields of Big Horn country is from Cheyenne to Fort Laramie and Fetterman, to which latter post the distance is 165 miles, with good ranches all the way. The distance from Fort Fetterman to old Fort Reno is 104 miles; from thence to Kearney 65 miles, and thence to Fort C. F. Smith 90 miles.

TAKING CARE OF CARRIAGES.—A precaution relative to the care of carriage, which is often overlooked, is to prevent rust of the spring plates where they are joined together and not covered with paint. The joints should be lubricated; and the best material for this purpose, where dark colors are used in painting, is composed of two parts each of pure beef and mutton tallow to one part black lead, well mixed, applied warm and in small quantities. When light colors are used in painting, diminish the quantity of graphite.

A PRINTER from Nebraska is on his way to the Black hills, and will start a paper at Custer City within a fortnight.

MECHANICAL PROGRESS

A New Form of Iron Furnaces.

Some time last year Mr. Alexander Royer and Mr. Naylor filed a caveat for a new form of blast furnace, the distinctive improvement being in the oval or oblong shape given the hearth, inwall and tunnel head. To make an experiment with a new form of furnace is exceedingly costly, so much so that but few persons can be found with either the nerve or the enthusiasm to undertake it. Yet there is no branch of business so needful of improvements as the iron business, nor one in which the theories on which it is based fall so short of being carried out in practice, all from the above reason. However, Messrs. Royer and Naylor have received many words of encouragement from practical iron foundrymen who have examined their models and plans, and several pledged some thousands of dollars for the building of one in the vicinity of Ironton and Ashland.

They claim that the oblong shape of the hearth, inwall and tunnel head with a stack of the present height of charcoal furnaces will effect a saving of at least one-half the charcoal used in a circular stack, but that by the construction of a stack only 20 feet high, with the hosh 10 by six feet, with the blast applied as shown in their models, i. e., by at least two tuyeres on each side, not quite opposite, but with each tuyere facing midway of the unoccupied space, and with a filling place above each tuyere, that metal can be made with only one-third the charcoal now used, and that more of it can be produced in the same time than by the present circular stack. They also claim that the proposed stack will make a more regular quality of metal, as the burden can be changed every four hours, or blown out, instead of taking 12 or 15 hours as now in the circular stack.

The expense of construction of one of these stacks will be not half so much as of the high circular form and the saving of two-thirds of the charcoal will not necessitate the building of extensive hot blasts. It is expected that the mode of filling and the shape of the stack will more equally distribute the ore and the fuel, secure more perfect combustion and utilizing every particle of the fuel to the best advantage. In experiments on a small scale 30 pounds of charcoal has produced 100 pounds of metal, or at the rate of 681 pounds of fuel to the ton of 2,268 pounds of metal. In practice not less than 2,440 pounds for hot blast, and 3,391 pounds for cold blast, are required to the ton of metal, a vast difference indeed, and one indicating that the best results cannot be obtained from the present form of stack. If the present form of stack can do what is claimed for it then it is an improvement the importance of which cannot be estimated, and we should like to see the experiment tried.—Ironton Com.

New Fuels.

In the manufacture of briquettes, or brick of coal-dust, for fuel, a slight modification of the usual Belgian process is announced. Instead of using water in making the coal-dust into a paste, a boiling mixture of tar and pitch is employed. To this is added sulphate of lime to remove the ammonia of the tar. The mixture is composed of 33½ parts of pitch, 13.6 of tar, and 1.80 of sulphate of lime, to one ton of coal-dust. The experiments going on in this department of fuel economy in this country have reached a practical stage in Pennsylvania, and fuel manufactured from coal-slag is already being extensively employed. So far, the reports are favorable to the quality of these American briquettes, and they are being freely introduced on locomotive engines. A French company is now extensively manufacturing kindling material for domestic fires by utilizing corn-cobs. Two processes are employed. By one, the corn cobs are first steeped in hot water containing two per cent. of sulphuric acid, and then saturated with resinous matter. By the other process, the cobs are soaked in a hot mixture of 60 parts resin and 40 parts tar. They are then dried, and afterward baked on a plate heated to 212° Fahr. Assorted and encased in bundles, they sell at the rate of four for an English halfpenny, or, at wholesale, for \$2 or \$3 a thousand. A process for utilizing corn-cobs by saturating them with resin has been patented in this country, and their manufacture has been attempted. The inventor already reports an active demand for them as domestic fire-lighters.—Scribner.

CARRIAGE WHEELS AND WHAT THEY CAN CARRY.—According to Mr. Henry Richardson, of York, Eng., the weight which carriage wheels are calculated to bear is governed by the circumference of the spoke, measured at half-way in its length. A spoke whose circumference at half-way its length is 3 inches, will carry 9 cwt.; 3x3 equals 9. So of any other diameter. A spoke 2½x2½ equals 7½ expressed in centals. By this formula the weight which any carriage wheel is able to bear safely may be readily calculated. It is further computed that: "A four-wheeled wagon traveling at three to four miles per hour will carry the full square of the circumference of the spoke of its wheel in cwt., over and above its own weight; a cart half the square. A carriage traveling at from six to ten miles an hour will carry the square of its spokes in cwt. of carriage and load; a gig half this.

Motive Power from a Permanent Magnet?

Mr. W. W. Gray, of Huntingdon, Penn., claims to have discovered a mode of utilizing the permanent magnet as a motive power. He claims to do this by the use of a cut-off or interpose, which neutralizes or cuts off the magnetic attraction and which is made to rapidly interpose and withdraw from between the magnet and the object attracted, which "object" would correspond in its effects to the piston of an engine. It has for many years been a study with Mr. Gray to discover or devise some element or compound which would defy, and by interposition, cut off the attraction of the magnet; all else would be simple. This discovery he claims to have made, and the same is verified by the editor of the *Huntingdon Journal* as follows: "We have tested it [the cut-off] in every way that could be suggested. We have taken a small piece of steel, placed it on glass, and then placed a magnet weighing perhaps a pound within attracting distance, and instantly the steel would fly to the magnet. We have placed the cut-off over the poles of the magnet, and placed it within the thickness of a hair of the steel, and it would not manifest the least attraction or motion. A needle suspended by a thread would fly to the magnet at considerable distance, but the moment the interpose or cut-off was applied the magnet could be placed within the thickness of a thread without any visible attraction. We have seen a pump, worked by magnets alone, pump water by the hour. Any force required can be supplied—from an engine to run a delicate watch or sewing machine to a power sufficient to propel the largest steamer." According to the above Mr. Gray accomplishes with a permanent magnet, which furnishes its own power at no cost except that of its original manufacture, just what has heretofore been done with the electro-magnet at the great cost of a battery to keep up its power. In Mr. Gray's alleged invention his "cut-off" takes the place of the "battery." If he has accomplished what he claims to have done what becomes of the new doctrine of "the correlation of forces?"

Bessemer and Its Uses.

The success which is attending the attempts to substitute Bessemer for iron in many branches of manufacturing and construction, is full of promise for this industry. We have hardly done wondering at one achievement before we hear of another. Where the first rude and crude attempts to use it proved failures later experiments have proved successful. We have already informed our readers of the successful manufacture at Troy of horse shoes and nails from Bessemer. The shoes, it is claimed, are lighter and wear longer and more even than those of iron, while the cost is not much in excess of iron. The nails, it is asserted, can be driven through oak planks and clinched.

We were shown yesterday a piece of hoop rolled by Wm. Clark & Co., from a crop end of a rail made at the Edgar Thomson. The flanges were bent up and welded in the ordinary way and rolled into the hoop, the strength of which was something marvelous. After a bending back and forward for ten minutes without any effort, we concluded to postpone any further efforts. The same hoop was riveted twice and tested, and sheared the rivets each time, but on the third trial it broke out at the side. The rail ends can be furnished at the price of muck, and the hoops can be made one-third lighter and still be stronger.

There is also a prospect that the Poughkeepsie bridge will be built of Bessemer. It was a favorite idea of the late J. Edgar Thomson that railroad bridges, especially, could be made of this metal, and an attempt was made in one instance, at least, to build a bridge of it, but was not successful on account of too high a temper. Now, with the improvements that have been made, it is possible to get almost any per cent. of carbon, and the attempt will no doubt now be successful.

A number of the steel and iron manufacturers of this city are gradually getting to use more and more Bessemer. One steel manufacturer has just given an order for 12 tons of ingots. Another has been using them steadily for months. One manufacturer of railway supplies expects to use 1,000 tons next year. These are indications that the steel age is coming.—Am. Manufacturer.

NEW COPPER PAINT.—The Paris correspondent of *Silliman's Journal*, states that M. Audry, who has been so successful in electro-plating with copper the cast iron monumental fountains in the *Place de la Concorde*, makes his new copper paint from the porous copper deposited by the galvanic battery, mixed with a varnish. The solvent of his varnish is the light and refined petroleum, or what we call benzine. The copper is very pure and is easily pulverized, then it is mixed with the benzine varnish, and applied either to iron, brass, plaster or wood. When this copper is mixed with oils, it acquires a green, antique hue.

THE American Manufacturer suggests that "the fuel of the future in the varied manipulation of the rolling mill will undoubtedly be gas. The question awaiting solution is the form of furnace which will be used. For the present, at least, in old works, and especially where bituminous coal can be procured at a low figure, the cost of Siemens will stand in the way of its introduction. In such works the aim will be to get some method by which the old furnaces can be used with little or no alteration."

SCIENTIFIC PROGRESS.

Prof. Tyndall on "Germs."

Prof. Tyndall recently delivered a lecture at the annual opening of the Royal Institution at London, in which he pointed out some of the possible practical bearings of the new "Germ Theory," when viewed in relation to medical science. The basis of the Professor's experiments is that, in the course of searching for means of obtaining air free from floating motes, he found that if air is allowed to remain in a closed air-tight vessel covered inside with glycerine, in the course of three or four days it deposits all its motes, which adhere to the glycerine, and it thus becomes quite free from them. The test of its perfect freedom is to pass a powerful beam of light through the case, when, if any motes are still floating, they make known their presence by reflecting the light. With air thus purified, Prof. Tyndall had made a long series of experiments bearing on the question of spontaneous generation and on disease germs. From these experiments Prof. Tyndall argues that sewer gas of itself is harmless; it is the germs floating in the sewer gas that sow disease. If there are no disease germs present, the gas does no harm.

Another set of experiments on the horizontal and vertical distribution of motes led to the conclusion that life germs float in little clouds, since an immense number of tubes exposed in different parts and at different heights in the laboratory showed that some were affected many days before others. Clouds of disease germs may explain a puzzle to surgeons—why a wound going on well for a while should suddenly, and without apparent reason, become putrid. It may be that it is being dressed just at a time when a "germ cloud" is passing. In his concluding remarks, Prof. Tyndall referred to the fact that it has remained for modern science to discover that, more than by battle, or accident, or famine, humanity suffers from disease germs conveyed in air and water.

What is Life?

At a recent session of the American dental convention, in the course of some remarks upon microscopic investigation, Dr. Atkinson said: "We shall never know anything about life until we go to the bottom of the matter of function. There is a substratum denominated 'atom,' which is the least manifestation of life that we know of. Atoms are endowed with life—they can't be killed. We have been told that the molecular life of our food is killed. A statement like that is either a *lapsus linguae*, or it shows an utter misapprehension of the subject. Atoms coalesce and manufacture molecules; plasma is an aggregation of molecules. Something must die that something else may live, throughout the range of organic life. We have crystalline life, and below that granular life, molecular life and atomic life. A crystal is regularly arranged granules that are regularly arranged atoms.

"The doctrine of inorganic or azoic existence will not do in this day. If we wish to know the origin of life, we must define the territory we are speaking of; when the conscious life has left the body, we have organic, cellular and molecular life left, and that is the food which we like to suck from the beefsteak. It is simply a polarization and depolarization of atoms that constitutes molecular mass. We cannot disrupt molecules without reducing to ultimate atoms; there is no such thing as death. Matter means mother. Every one who has followed me knows I have given as complete an answer to the question we are discussing, as that two and two are four. When the blessed love of the Father of Light comes in and illumines us, we are endowed with the capability to perceive. The doctrine that *omne vivum ex ovo* is pretty old, as old as Harvey. If the protoplasmic mass is an egg, that is true; there are no bricks without mud, there is no loaf without dough. What do Bastian's investigations prove? Only that these points are so small as not to have been detected before; they do not prove that the germs are not essentially eggs. What is an atom? It is in size about the two hundred millionth part of an inch. If one side of it is warm and the other cold, there is polarization and depolarization, and that brings it to a point where freezing begins, and that is crystallization. When we have investigated deep enough, we shall be prepared to understand the processes, and they will be as plain as the freezing of water."

AN IMMENSE TELESCOPE.—A telescope is now in course of construction in Dublin, says the *Montagszeitung* of Berlin, for the observatory of Vienna. It is to be 32 feet in length, have an objective glass of 26-inch diameter, and the large brass case, weighing eight tons, is to have a chamber 12 feet in length and 4½ feet in diameter. The tube is to be entirely of steel, and all friction of the axis will be avoided. The instrument is to be finished in 1878. Telescopes have been made of such magnifying powers as to enable those using them to detect bull-lings or works, if there were any, in the moon, so large only as Westminster Abbey; so that anything like cities, or roads, or masses like armies, for instance, in motion, would easily be seen. But nothing of the sort appears to the keenest eye.

Recording and Photographing Sound.

Prof. Vogel, in a letter to the *Photographer*, Philadelphia, Pa., says that Konig, at Paris, has constructed an apparatus, consisting of a little drum, over which is stretched a very elastic skin. A stream of gas let through this drum will born as usual; but as soon as a tone (by singing) strikes the skin stretched over the drum, the gas light commences to shake in a wonderful manner; and if we look at it in a rotating mirror, we observe peculiar figures, which change according to the different notes; and by using a burning gas producing a light of great chemical effect, we can photograph these peculiar figures. What kind of gas will answer for this purpose is still an undecided question, but this much is certain, there are in this respect great problems yet to be solved; we may succeed, perhaps, in photographing speeches instead of stenographing them as usual.

In connection with the above it may be interesting to read the following mode of

Recording Musical Performances.

A mechanic of Bridgeport, Conn., has invented an electrical apparatus which records musical sounds as they are played, which has been successfully applied to an organ at New Haven. The organ is connected with the recording apparatus by a music telegraph, and its operation is very simple indeed. Beneath each note of the three manuals and of the pedals, and connected with each stop of the organ, is a small brass spring, which is pressed down whenever the piece to which it is attached is brought into action. From each spring wires run to a galvanic battery of 12 cells, and to the recording apparatus, which may be situated at any convenient distance from the organ. When the spring is pressed down, connection between the battery and recording apparatus is opened and the electric current passes through and is made to impress a paper very much in the same manner as the ordinary telegraphic machine.

We may also call attention to an apparatus for transmitting musical tones by telegraph, concerning which an item has been traveling the rounds of the papers, and which depends upon the well known principle that the difference in musical tones consists in the difference in the number of vibrations in the air in a given time. The invention consists in transmitting a series of impulses of induced electricity of high tension, corresponding in number to the number of audible vibrations constituting a given musical tone through living tissue in contact with any resonant substance, or through a coil surrounding a bar of iron or the core of an electro-magnet, the succession of currents being produced by an induction coil or other apparatus for inducing a secondary current, and being caused by the action of any suitable circuit interrupter situated in a primary circuit.

We agree with a contemporary that it would appear from the above and numerous similar recorded instances that there is a growing tendency to complicate machinery by the introduction of electric contrivances, which in many cases are utterly uncalled for and unnecessary.

A New Classification of Elements.

For some time past the Russian chemist, Mendeleef, has proposed a classification of simple substances which satisfactorily details the leading properties: atomic weight, density, point of fusion, etc. He has discovered that all these bodies form perfectly regular series, and that given the first term of a series, the properties of the bodies forming the succeeding terms may be accurately determined beforehand by means of certain coefficients. In the series which he has thus classified, and which include all the known bodies, there are several gaps, but the Russian savant, certain of the correctness of his views, maintains that, sooner or later, chemical discovery will determine the existence of bodies still unknown, the principal properties of which, however, he is enabled to foretell.

It is a remarkable fact that the new metal discovered by M. Lecoq, of Boissandran, and called by him *Gallium*, fills one of these gaps, and, according to what is actually known of its properties, they quite coincide with those predicted, in accordance with the new theory, for a metal to which the name of *Ekaaluminum* had been given. The new metal has a considerable analogy with zinc, though whiter and more brilliant, and approaching silver in appearance. M. Lecoq has, however, only been able to obtain it in very small quantities, which are not sufficient to determine all its properties.

SOLAR PROTUBERANCES.—At a recent meeting of the French Academy P. Secchi presented still another of his reports of observations of the solar protuberances and sun spots, the period of observation being from April 23d to June 28th, 1875. He records the extent of surface of the spots (according to a method described), instead of the number, as formerly. He finds *inter alia* that the daily number of protuberances and the surface of the spots have gone on steadily decreasing; that the large eruptions ceased when the large spots disappeared; that the maxima of protuberances at the poles had disappeared, as also the faculae which had collected round the poles, forming coronae; and that lofty protuberances were becoming very rare. It appears, then, that we are now near the minimum, and that an increase may be expected shortly; and P. Secchi invites astronomers to carefully note the phases of this increase.

There has been some little advance in mining \$820,000 by the Belcher and Crown Point.

There has been some little advance in mining stocks during the past week, mainly confined, however, to a few stocks. The greater portion of the list shows little animation, although everybody is waiting for this long expected "spring rise." The Bonanza mine continues \$820,000 by the Balch and Crown Point. The Dancy Mining company is this last so far to increase its capital stock. A meeting will be held on the 27th inst. to decide on a proposition to increase the capital stock from \$2,400,000 in 24,000 shares to \$10,800,000 in 108,000 shares, of the par value of \$100 per share.

to send down large amounts of bullion, the yield for this month reaching nearly \$3,000,000—an immense amount for a single mine to turn out. The immense production of this mine is having a very great effect on the finances of the nation. It is stated that during the past week the Government bought from two of our largest banking corporations 300,000 ounces of the fine silver contained in bars at \$1.16 per ounce, the sellers paying the parting charge of 2½ per cent., which makes the price of the fine silver about \$1.1333 per ounce. It is believed that this is the lowest price ever paid for fine silver in the United States. The standard value of

Our stock tables show the number of shares sold and highest and lowest prices of prominent stocks for the past week. A slight examination will also show the highest and lowest prices for the month passed.

Thomas M. Blair, for 13 years Serasant-at-Arma of the San Francisco Stock and Exchange Board, left on the *Mikado* for Honolulu on Tuesday. His hasty departure was caused by the advice of physicians, who told him that one of his lungs was entirely gone, the other badly affected. Just before his departure a subscription was taken up in the Board room, and in half an hour he was made happy by the receipt of \$12,500. A generous set, the brokers

fine silver is \$1.2929 per ounce. This purchase will be immediately coined into subsidiary coin for Government account. It is now said that the Government contemplates redeeming the fractional currency with silver.

Dividends from Anderson Lumber Co. are \$1,386,000, of which the Consolidated Virginia paid \$1,080,000. The amount paid in dividends during the corresponding month last year was \$638,700, of which Consolidated Virginia furnished \$324,000. The great gain is chiefly owing to the increase of that company's dividends from \$3 to \$10 per share. In February, 1874, the total dividends of local incor-

porations amounted to \$1,233,800, of which mining companies paid \$855,000, including \$820,000 by the Belcher and Crown Point.

The Dansey mining company is the last so far to increase its capital stock. A meeting will be held on the 27th inst. to decide on a proposition to increase the capital stock from \$2,400,000 in 24,000 shares to \$10,800,000 in 108,000 shares, of this par value of \$100 per share.

Our stock tables show the number of shares sold and highest and lowest prices of prominent stocks for this past week. A slight examination will also show the highest and lowest prices for the month passed.

THE *City of Panama*, which arrived here on the 21st ult., brought down from Victoria several specimens of the native woods of British Columbia, among others a cross section of the Douglas pine. This section measures 27 feet in circumference.

NEARLY all the mining claims in Jackson county, Oregon, heretofore worked by the Chinese, have been jumped by the Whites.

THE 'Alhion mill company in Mendocino county will saw 16,000,000 feet of lumber the ensuing year.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

THE PLUMBOCK ROCK MINE.—*Amador Ledger*, Feb. 27. A correspondent writing from Plumbocock on date of February 27th, gives the following information concerning the quartz ledge recently discovered near that town: "The gold-bearing quartz ledge discovered some time ago by John Evans is developing nicely. The owners feel much encouraged, and the citizens begin to look upon it as an important accession to the resources of this place. This claim has been named the Plumbocock Rock mine, and is worked by John Evans and Philip Kleres. They intend to sink upon the ledge to the depth of 100 feet, and then drift. The shaft is now 40 feet deep, and the ore body continues to improve as depth is attained. The ledge at present is over three feet in width. Since the first of January there has been taken out about 45 tons of good paying rock, which it is expected will average between 95 and 110 per cent.

CLEAN-UP.—The clean-up of the crushing of the rock from the Moutierichard mine, two miles from Jackson, averaged \$15 per ton. Nine tons were crushed at the Kearing mill, with the above result. The owners talk of securing new Stephen Kendall's mills.

MAXIMUM DEPTH.—This property begins to form up of the future mines of the county. A rich vein of quartz, varying from 18 inches to two feet in width, has been cut, which is expected to yield something like \$30 to the ton. Some of the rock has yielded as high as 60 cents to the pan. It is the opinion of some mining experts that the gold obtained in such large quantities by placer mining in the locality of this mine in early days, came originally from the ledge struck in the Maximilian. As an example of confidence in the permanent nature of this mine, we may mention that S. S. Maun, of Sutter Creek, has expressed his willingness to put up a 10 stamp mill, and rely upon the proceeds of the crushing for his pay.

CALAVERAS.

RICH ROCK IN THE GWIN MINE.—*Calaveras Chronicle*, Feb. 25. We learn that rich rock has been struck in the 100-ft south level of the Gwin mine, at a distance of 95 feet from the shaft. The ledge is over four feet in width, and we are informed that it is composed of so good rock as has yet been found in the mine. The quartz is so excessively slow that the work of running the level is necessarily slow and tedious, but in a short time it will have been driven far enough to permit of an uprise preparatory to stopping.

GRAVEL MINING.—A visit to the numerous gravel mining enterprises in this vicinity develops the fact that operations are being pushed with exceptional briskness, even for the winter season. All the claims are being steadily and energetically worked with results that, generally speaking, are eminently satisfactory. There is abundance of water, and as ample preparations were made during the dry season for active operations through the winter, the claims are all in condition for working to the best possible advantage. Quercel & Co., proprietors of the "Old Boh Pea claim," in the Chille gulch, continue to take out rich gravel. The mine is worked through the new incline run last year, and the gravel is being raised by means of a hoist and hoisted as ever. The gravel has to be hoisted, dried and pulverized before it will wash, and yet it is so rich that the mine is paying handsomely. Two tunnels are being run in the well known Durfee claim, the object being to ultimately connect them for the purpose of permitting the employment of a large force of hands in hoisting. Each tunnel is being worked with a good track and cars, and as the headrock pitches into the hill, animals are employed in hauling the gravel upon the incline to the dumpbox. When the new system of working the mine is fully developed it will unquestionably prove as remunerative as it did during its palmy days as a hydraulic. In Cook & Co.'s hydraulic, at Red Hill end on the Calaveras, panning is going steadily forward. Every claim is progressing favorably, and the prospects are flattering that the season will prove a remunerative one to the company. Nons deserve better success than Cook & Co., and we hope the only thing that will bother them in this world will be what to do with their money.

FRESNO.

OLD BEARING QUARTZ.—*Fresno Examiner*, Feb. 23. During the past week a number of excellent specimens of gold bearing quartz, some of it very rich, has been shown to us. John Oden, of Borden, showed us specimens which he obtained from the vicinity of the old Claims Mader mine, on the north side of the San Joaquin. The specimens showed a considerable quantity of the gold. Mr. Oden informed us that he had found a very well defined vein of quartz, from which he had obtained his specimens. Washington Armstrong and John McDowell, who live near the head of Big Dry creek, left with us some specimens of rock, literally spangled with gold. These specimens they obtained from a quartz ledge found near the head of Big Dry creek. They traced the lead nearly a mile. They also had some two ounces of quartz gold, which they had obtained in the bed of a ravine through which the ledge passed. The Confidence mine, situated on the Fresno river, owned by James F. Dodds and others, we are informed, still continues rich and promising. The Champion mine, owned by Keyes and Jensen, has been panned to a depth of more than 50 feet. The ledge is well defined and increases in width. The quality of the ore continues to improve all the time, and it is now established beyond a reasonable doubt that the mine is rich and extensive. The last crushing of ore from the extension of the Champion, and owned by Smith and others, we learn gave a yield of nearly \$50 per ton. With the unlimited number of quartz veins that permeate the foothills of this county, nearly all of which show fine gold, it seems strange that many paying quartz mines had not already been developed in Fresno county.

INYO.

PANAMINT.—*Tulare Times*, Feb. 26. A gentleman who has the best of opportunities of knowing, told us a short time since that the Surprise Valley company are highly elated at the magnificent development lately made in the Hemlock. At a depth of 400 feet, the lowest point reached, it shows a regular bonanza, eight feet wide of the richest ore for the mass they have ever found. The company, we understand, do not expect to stop short of 1,000 feet, or another Constock. The Wyoming does not clement materially, being down about the same as the Hemlock, but at which point it is full as good if not better than at any previous one, therefore great hopes are entertained of something more. Further progress in the Hemlock is being made exclusively on company ore, although an occasional custom lot has been worked. Its average production up to January was very nearly \$50,000 per month, produced at a cost of \$30,000, leaving quite a handsome profit for a starter. Dave Nagle had a lease of the Jacob's mill, and was running it successfully on ore from a mine of his own, the name of which we have forgotten. Panamint is considered as decidedly on the up grade.

DEFANCE. (Coco District).—*Coco Mining News*, Feb. 24. The drift being run from the south drift on the 60-ft level has been driven about 40 feet, all the way through an exceedingly rich body of ore. On the 80-ft level a drift of about the same length has been run south through the same body of ore found in the level

above. The width of this body is, as we stated in our last issue, unknown, and, of course, cannot be ascertained until a cross shaft has been made in the same. As to the length, we can only say that it has been explored a distance of more than 200 feet. In every opening in the mine large blocks of glittering galena met this eye.

DEFANCE.—The mine has been running very successfully during the past week. The company shipped since the 16th inst. 600 bars bullion, and has on hand 200 more. The bullion continues of high grade.

CARLOTTA MINE.—Another rich strike has been reported to us from the Lookout district, by Messrs. H. Shattman & Co., of the above named mine. The Carvella is situated about seven miles from Darwin, on the main belt of the above range near the summit, and about four miles from the spring in the Darwin wash, owned by Mr. E. Reddy. It is pronounced by reliable parties to be one of the richest discoveries ever made in that district, and the owners feel highly elated over their strike. Starting from rich galena croppings a prospecting shaft was sunk of about six feet, disclosing a ledge of about four feet in width of almost solid galena ore, mixed with grey carbonates. The parties have now already about five tons of ore on their dump, which will assay from \$200 to \$300 per ton. It is their intention to continue the work on so valuable a mine, but being in rather limited circumstances, as prospectors generally are, it is a matter of grave doubt if hoisting works will ever make their appearance. The ledge is very large, and the ore is of a fine, larger than their own, in the further development of their property.

NEVADA.

AMERICAN MINING CO.—*San Juan Times*, Feb. 26. The junior of the *Times* made a flying visit of observation to the American mining company's claims on Monday last. The company are working their claims in a thorough and vigorous manner. There are three large pipes used in washing their claims, one at the Gold bluff claims, one at the old Badger company's claim and one at the American claims proper, all of these claims belonging to the American company. The company have about 1,800 inches of water per day, through three immense monitors, which throw the water with powerful and effective force against the benches of the claims. The company are running a new tunnel into their claims, which, when completed, will be about 9,225 feet. There is in the neighborhood of 100 feet of tunnel yet to run, which will be finished in about two months. The company have been working a new tunnel in sinking shaft on the new tunnel, but owing to the water running in so rapidly had to stop working the same; about three or four weeks ago work was again resumed on the shaft, the water having drained out through seams in the rock to the tunnel below, and in a short time the shaft will be completed. The company have now about 50 undercurrents connected with the main shaft, and are clearing the way for two more, 24 feet wide each, to be placed next to the Middle Yuba river. Four more undercurrents will be built soon. Sixty men are employed in working these claims, under the charge of George C. Spooner, Esq., all white men. No Chinamen are employed. The claims are worked night and day.

THE MINES.—*Grass Valley Union*, Feb. 26. We are clearly impressed with the conviction that the mining business of Grass Valley, in the coming spring, will be unusually brisk. We say this because there are many prospectors at work, and most of them are taking out ores that will pay. The early prospect that a process, by which almost all the gold and silver in ores can be saved, will be in active and successful operation, has caused this renewed interest in the matter of prospecting. Besides the prospecting, the company are working a mine that is being worked with success by mill process. Ideo is yielding steadily and regularly, and will be ready for the next dividend. The ore in the mine shows that pay is there for years to come. The Eureka, although not paying as she once did, has hopes of good success before her. We believe that the Morehouse ledge, and being prospecting by the company, will develop the body of ore to which is the district in which the gold has taken. Omshe has lately given a good account of herself. Those mines down the creek, as the Omshe is, appear to be looking up, after years of idleness and neglect. The Omshe is one of them. Splendid ore is now coming out of the lowest depths of the mine, and all agree that the ledge increases in strength and in quality. Everything is progressing favorably, and the prospects are flattering that the season will prove a remunerative one to the company. Nons deserve better success than Cook & Co., and we hope the only thing that will bother them in this world will be what to do with their money.

PLACER.

COMPLETED.—*Dutch Flat Forum*, Feb. 24. The Badger shaft, passing down through the Badger claim a distance of 150 feet, to a branch run off from the Yankee tunnel, is completed. The connection was made on Saturday. This shaft intersects the Yankee tunnel about 1,200 feet from its mouth. The rock has been very hard and the progress slow, but as is always the case where there is any pay, the work was persevering, the object is accomplished. This is another step in the progress of the extensive developments being made by the Cedar Creek company under the management of Col. T. B. Ludlum.

GRAVEL MINES.—Since the storms have abated, and clear weather has set in, our various miners display their usual vigor in resuming the work of the various claims. The water is so low that it could obtain well, resumed washing, and are now panning away. The Elmore Hill claim continues washing without interruption, only turning off to clean up or to change the position of the plants. The Central claim has resumed washing and is running night and day. The Jehoshaphat claim is idle at present, pending the running of a shaft. The water is so low that it could obtain well, resumed washing, and are now panning away. The Elmore Hill claim continues washing without interruption, only turning off to clean up or to change the position of the plants. The Central claim has resumed washing and is running night and day. The Jehoshaphat claim is idle at present, pending the running of a shaft. The water is so low that it could obtain well, resumed washing, and are now panning away. The Elmore Hill claim continues washing without interruption, only turning off to clean up or to change the position of the plants. The Central claim has resumed washing and is running night and day. The Jehoshaphat claim is idle at present, pending the running of a shaft. The water is so low that it could obtain well, resumed washing, and are now panning away. THE ENGINEER.

The Genesis of Architecture and Engineering.

Architecture and engineering, until within a comparatively recent period, mingle at so many points that they can scarcely be said to have a separate history. Indeed, until about the fifteenth century, it may be said that neither had any history at all, save that which has been derived from observation of the remains of architectural and engineering works. In early times opportunities for the interchange of knowledge were few, while the means for recording the same were still more limited; in fact, the means for permanent record were wanting altogether. Hence the slowly accumulated results of the experience of the early centuries was altogether lost during the political and dynastic revolutions which preceded the glory of Greece and Rome; and but little of the wisdom of even those later empires has survived the wanton destruction of the dark ages which succeeded their downfall.

Passing by the early attempts at design and construction, which merely supplied the necessities of man, architecture and engineering doubtless had their origin in ancient Egypt, and were carried from thence to Chaldea and Babylonia, afterwards passing into Greece, Carthage and Rome, and finally through Asia and across the Northern plains of America, down the Mississippi valley to Central and South America. The Egyptians have left no record of how they accomplished their difficult works of transport and lifting. Neither have any of their successors, save the Romans, from whom we have derived but faint and imperfect ideas.

The Egyptians must by some means have lifted vertically into place obelisks weighing upwards of 400 tons. They transported, from a considerable distance, at least in one instance—the statue of Rameses the Great—a stone block which weighed over 800 tons; while a block still lies in one of their quarries squared and evidently intended for transportation entire, which weighs not less than 1,135 tons! In India stones weighing 25 and 30 tons are found forming pyramidal roofs, at a height of 70 and 80 feet from the ground. Similar weights, but not at so great a height, were lifted in Persopolis, during the reigns of Xerxes and Darius. The early Chinese appear to have been more careful of their strength or more lacking in skill; for although they moved very heavy blocks for building their bridges, which are almost always permanent structures of stone, they took care to have them only of moderate dimensions. But the Peruvians, whose ancestors—the Western mound builders—must have come over from Asia, brought with them much architectural and engineering skill, for we find that they employed blocks of from 15 to 20 tons, which they must have carefully lifted and fitted with the greatest nicety in their well designed work.

The only modern effort at moving such excessively heavy blocks is the case of that which now forms the base of the statue of Peter the Great, at St. Petersburg, in Russia, which weighs 1,200 tons. There can be no doubt that people who were capable of erecting such works as have come down to us from ancient Egypt must have possessed a large amount of engineering and mechanical knowledge. Those people were pyramid and temple builders for at least ten centuries, as we know from undoubted records that have been preserved; and their skill and knowledge must have been cumulative. That they had a knowledge of iron and steel has been of late years well substantiated. That the Assyrians at least were acquainted with the pulley is known from the fact that one of their tablets recently exhumed shows a man drawing water, as if from a well, over a single pulley block. If the single pulley was known, why not the double and compound block? If known to the Assyrians, it could scarcely fail of being known to the superior race which inhabited Egypt. Another tablet informs us that they had a public officer who was known as "the master of the works;" so that there must have been even in those early days an intelligent division of labor. Under the Roman empire there was almost or quite as great a division as now exists in our perfected system of labor and design. In Vitruvius' *De Architectura*, we find among other things a chapter on machines for raising and transporting great weights, and even on the construction of looms.

Although the Egyptians have left no record of how they accomplished their great works, it is quite certain that their long experience must have proved such a tax on their ingenuity, as in all probability to have led to a comparatively perfected skill in, and knowledge of, even many modern mechanical appliances.

They build so well that many of their works have come down to us through more than 30 centuries, so perfectly preserved that our imagination readily creates, with more or less of probability, the devices and methods by which they must have wrought. Of even the later structures of Greece and Rome, whose people were largely in advance of their predecessors, and who built with complex arch work

and stairways, and beautified with accurate elliptic lines of curvature and various ornamental works of elegant design, we know little or nothing as to what were the methods, or how the stone cutter was so guided in his intricate work as to make each piece fit accurately in its place in the complicated whole. We know much historically, and by studying its remains, of the Parthenon, but we know little or nothing of the technical methods employed in cutting or putting in place its magnificent columns.

Did the architects of those days lay out their work by the same rules as are now followed? Were their designs drawn on parchment, on wooden panels or waxen tablets? Of all this we know nothing. But we do know that architecture had at that time reached a point of perfection which has never since been equaled.

But the labors of the ancients were not confined altogether to temples, palaces and tombs. Works of utility, canals for irrigation and for internal commerce were also undertaken on a scale quite as gigantic as were their architectural works. Traces of many of those works still remain, which, when compared with the few records that have come down to us, show that engineering, as well as architecture, had no existence in pre-historic times.

The irrigation works of Egypt 3,500 years ago will compare favorably with any of modern date, both in perfection and extent. One of their reservoirs was 150 square miles in extent, and maintained by a dam 30 feet high, 180 wide, and at least 13 miles long, and was capable, and no doubt did, irrigate an extent of more than 1,300 square miles of country, or a region about twice as large as the entire San Joaquin valley, in this State.

The same people excavated, and for ages used a ship canal from the Red to the Mediterranean sea. M. de Lesseps did but little more than open up anew this ancient canal.

The Babylonians also had their canals for the double purpose of commerce and irrigation, one of which has lately been traced for a distance of nearly 500 miles. These people always planted willows—or a tree similar to the willow—along the banks of their canals. It was upon those "willows" and along the banks of the smaller irrigating canals that the children of Israel hung their harps when they became too despondent to enjoy their music during the long years of their captivity.

The Assyrians, also, constructed large irrigating works. Owing to the uneven face of their country they were of less extent; but for the same reasons required far higher engineering skill—such as tunnelling through rocks and hills, and building dams of solid masonry by which to take the water out of their swift flowing rivers.

The irrigating and immense navigable canals of China, many of them built in very early ages, still exist, as do their immense walls, bridges and aqueducts.

How were engineers educated who constructed those immense works, and what were the instruments and appliances with which they were enabled to accomplish them? We know that the Egyptians at least had some knowledge of surveying, for an ancient author tells us that they had maps on which they recorded their marches. Recent researches in Assyria have also made us acquainted with the fact that the Assyrians had, among their titled men, a "Lord of Canals" and the "Establisher of Irrigation Works."

The magnificent aqueducts, tunnels, roads and works of defense of the Romans and Etruscans are familiar to us in their ruins and in history, which assure us that the art of engineering was well understood by those under whose direction they were constructed; but all knowledge of modes of designing and methods and appliances for construction have been lost to the world. The genesis of architecture and engineering dates far back into the early history of man. How many centuries were required to arrive at the degree of perfection made by the cotemporary of Abraham we know not; but we do know that very little progress was made from that time for nearly 2,000 years afterwards, and that what was gained during the supremacy of Greece and Rome was lost quite as speedily as it was won.

Modern engineering dates from the revival of the arts and sciences in the 12th and 13th centuries, and will form the subject of another chapter in a future issue of the Press.

A NEW SCHEME FOR CROSSING THE MERSEY.

A large and influential meeting was recently held in Liverpool for the purpose of inspecting the plans prepared by Mr. Morton, C. E., for crossing the Mersey by means of an iron tunnel, to be sunk at the bottom of the river, in a line between Liverpool and Seacombe. The scheme embraces the excavation of a trench in the bed of the river to contain the iron tube, which will lie at a depth of about two feet below the bed. This excavation is proposed to be effected by means of large air chambers on the principle of the diving bell. A certain amount of flexibility will be given to the tube by the use of Mr. William Williams' patent joints, which will enable it to be lowered down in sections when the trench is completed. It is proposed to have the Liverpool station at the top of Dale street. From here a tunnel will descend by easy gradients to the river side, join the tube near the Landing Stage, and so on to Seacombe, where it will branch off to Birkenhead, and effect a junction with the Great Western railway there. The cost of the work, exclusive of station buildings, is estimated at £500,000.—*Iron*.

Heating of Journals.

Engineers in charge of machinery and steam engines are constantly troubled by hot journals. In ocean going steamers these may occur during the whole voyage, and it is not an unfrequent practice to allow water to run on crank pins and large journals the whole time the machinery is in motion. With locomotives and steam cars, however, running water constantly on the journals is impracticable, and some other expedients have to be adopted. Plumbago and oil, sulphur, soft soap, and a variety of ingredients have been used by engineers with more or less success. The heating of journals may arise from several causes. The shafts may be out of line, dirt may have got into the boxes, there may be too much thrust on the flanges of the bearings, or by neglect in oiling the journals may have got dry. The desiderata are how to cool the journals and how to keep them so. An old remedy for cooling large journals, and one that seldom fails, is, first wash out the journal and boxes as far as practicable by means of a water hose; lubricate slightly with good oil; remove the oil cap and insert in place of it a tin or copper tunnel; fill this with soft soap and water, of such consistency that it will drop freely from the tunnel tube on to the journal, until it is completely cooled. The soft soap lubricates and at the same time the water cools. This plan has not the objection of sulphur and black lead, which cake on the boxes, and to some degree cake and grind on the brasses.

A patent has recently been issued for a new lubricant, which, it is said, has already come into extensive use, and has been recommended by numerous engineers. The material consists of a fine white powder made from a mineral of talcous magnesian character, free from grit, and is ground and bolted especially for this purpose. When applied, three or four pounds of the lubricant is well mixed with one gallon of oil. This mixture will not become gummy, and is found to be equal in service to about three gallons of the best oil. With new car journals the cellar of the box is filled with waste, well saturated with oil up to the bottom of the journal; then a stiff paste of the lubricant is made with lard or any other oil, and the remaining space around the journal is entirely filled with it. The lubricant is perfectly incombustible.

Railways at the Bottom of the Sea.

When railways on land were first talked of, the projectors were credited with being visionary enthusiasts. What, then, is likely to be thought of those who seriously propose to have railroads under the sea. A submarine carriage of a most ingenious construction has recently been invented in Paris to cross the channel, and for navigating deep rivers and canals. The carriage is of galvanized iron, and is hermetically sealed. As its lightness, compared with surrounding water, would cause it at once to rise to the surface, it is attached to a heavy eight-wheeled truck, which runs on a line of rails laid down under the ocean. It is not fastened so securely, however, but that, in the event of an accident, it could be at once detached and allowed to ascend to the open air, when it would be easy to make for the nearest port. The motive power is supplied by two screws driven by compressed air. An enormous quantity of air is distributed through the interior in numerous pipes, for the benefit of the screw and passengers. We might enter still farther into details, and describe the electric light at the bows, which is to illuminate both the road and the interior of the vessel; the entrance for the passengers, hermetically sealed when all are aboard; the strong glass windows, out of which any one may see the marvels of the deep; the raft carried on the roof, and the divers' chamber at the stern.—*Manufacturers' Journal*.

RESERVOIRS FOR THE MISSISSIPPI.—In order to do away with the enormously destructive freshets which occur every spring along the course of the Mississippi it is proposed to establish a system of reservoirs above the falls of St. Anthony, by building a number of dams to withhold the water from the river in spring and utilize it when necessary. From surveys recently made by United States engineers it appears that the area of the water sheds, or affluents of the great river above the falls of St. Anthony, is 19,903 square miles, which might hold, besides the present supply, 95,500,000,000 cubic feet of water. At low water there is a deficit at St. Paul which might be supplied from these reservoirs and the flow be kept even, or at such a rate of motion as might be required. The time will probably soon come when human providence will deal with the Mississippi—the Nile of America—as the ancient Egyptians dealt with their sacred river. One of the wonders of the engineering skill of those great people was the Lake of Mæris by which the inundations of the Nile were regulated and water stored up for irrigation during the low stage of the river. With such reservoirs as now proposed an equally great and admirable work might be accomplished in America.

STILL ANOTHER MAMMOTH ENGINEERING PROJECT.—The union of the Black and Caspian seas is in contemplation, and a project for the construction of a canal 750 miles in length for that purpose is said to be finding much favor in St. Petersburg and Moscow.

The Santa Rita Placers.

The *Arizona Citizen* says: Mr. Herman Welisch was in town from the Santa Rita placers this week, on a short business visit. Mr. Welisch is a merchant at the placer settlement, has been there for four or five months past, and has had the best means of ascertaining the value and extent of the gold fields and permanency of the diggings. He says there is entire ignorance here in the matter of these placers. Certain parties have gone there expecting to find gold as it was found in early days in California, in great abundance on top of the ground, and to be obtained for this picking up, and of course were disappointed and have left the fields carrying evil reports with them. Those who have staid there and been willing to work are making money, and, even under the discouragement of an entire absence of rain since September, are becoming more and more encouraged at the prospects and results of their daily toil.

These placers are not surface diggings, although considerable gold has been found at a shallow depth. But developments have proven that to get at the heart of these deposits the stripping and drifting must go well into the earth. After getting the pay dirt, the difficulty is the water. But here again, the miners have found that hard work will counteract the difficulty to an extent. Every camp, of which there are about six, with some 350 miners, has its reservoir, and two good rains during the rainy season will furnish sufficient water for present demands, during the next ensuing five or six months.

Mr. Welisch says that he estimates that between \$60,000 and \$80,000 have been taken out in gold dust in these placers for the one year they have been worked. Given a good rainy season and he believes the fields would produce an average of \$1,200 per day, with the present working force. Space will not now permit a description of the different camps and leading men. There is plenty of hard work and good pay. Living is as cheap as in Tucson. Mr. Welisch says that flour is sold there with a slight addition for freight over town price, while other provisions, clothing and dry goods average as low as Tucson prices. The scarcity of rain has compelled more extensive digging for water, with blasting, resulting in considerable success.

There can be no doubt of the value of the placers, but work is required. One man in three months took out \$8,000. This is an isolated case, but there are many cases of less and yet large success. Fred Hughes lately started drifting on a hill which others had abandoned because they could not find gold with a penknife, and in one day's work took out \$16. We shall yet hear great tidings from the Santa Ritas.

Consumption of Lead.

There is not a single lead mine west of the Rocky mountains—that is, a mine worked exclusively for lead ores. Yet the base metal ores on this side of the country furnish about half of all the lead used in the United States. According to a statement in the *Iron Age*, 61,473 tons of lead were produced in the United States during the year 1875. Of this amount 31,200 tons were produced from base metal ores from west of the Missouri. The lead was taken out at the reduction works in Chicago, Omaha, Salt Lake, San Francisco, and at the smaller smelting works connected with silver mining companies. The aggregate supply in 1875 fell short of the preceding year about 7,000 tons. The consumption of white lead last year in the United States was 45,000 tons. The consumption of lead is rapidly increasing. Vastly more is used for plumbing purposes than ever before.

There was a time after the close of the Franco-German war when the lead market became very dull. Considerable lead which had been bought for war purposes was put on the market. This was also true after the close of our civil war. But more recently the leading nations of Europe have been putting their armies on a war footing. These movements will prevent the placing of "war lead" on the market. Russia last year imported 16,000 tons of lead from Western Europe, Spain in time of peace, produces about 65,000 tons of lead annually, or a little more than the United States. But during the last three or four years the production has fallen off on account of the civil war which has been raging in that country. The lead mines of the Western States produced in 1875 only about 22,000 tons, less by 9,000 tons than were extracted from the base metals in the States and Territories west of the Missouri. A few years ago the miners did not know what to do with a base metal mine. Now they know that the presence of lead insures the easy and profitable working of all such ores.—*Bulletin*.

THE FRYER PROCESS.—The Nevada *Transcript* says: We understand there will be a foundry with a capacity of turning out one "process" a day erected soon, at the Fryer works. We hear that a large quantity of freight is now ready in San Francisco for shipment to the same works, which will be used in the erection of extensive works, that will—in the course of the next two or three months—be put up. Mr. Fryer has concluded to have all his work done in this county, and keep his general office here also. Few are aware of the benefit which will be derived by the county from the establishment of such works in our midst. The railroad is convenient to the present works and a side track will soon be run up to them for the more convenient handling of heavy material.

USEFUL INFORMATION.

Refrigerating Railroad Cars.

Any practical method for refrigerating a railroad car so that the temperature may be kept constant at about 40° Fah. will be of immense service for transporting fresh meats, fruits, etc. Efforts have been made to accomplish this by packing ice in the car with the fruit, etc., and trusting to an ordinary ventilator, operated by the speed of the train, for a constant supply of air from the outside to be cooled by the ice before coming in contact with the fruit. But this method has been found very uncertain and expensive, by reason of the large amount of ice consumed by the constant influx of warm air.

A new plan has recently been adopted which is said to be meeting with very good success, and which is described as follows: The car is provided with a fan-blower, driven by one of the axles, by means of which air is forced over the ice and thus reduced to a low temperature. This chilled air is distributed among the fruit boxes through a large perforated pipe laid along the bottom of the car. After it has thus circulated among the fruit, it returns to the blower, and is again forced through the apparatus. By this means the atmosphere of the car is said to be kept at the desired temperature with a very small consumption of ice.

CASTING STOVE PLATES.—As the stove plates of to-day are more or less elaborately ornamented with finely relieved patterns, having sharp corners, and oftentimes with extremely fine lines of depression and elevation, it becomes necessary to use the utmost art and care to have the work as near perfect as possible. To accomplish this, and give the finest possible surface to the casting, beeswax is applied to the patterns. This is done in the following manner: The pattern must be heated till it is hot enough to melt the wax and not burn it. Then apply the wax by rubbing it here and there over the surface of the plate; a small quantity only is required. After which, and while the wax is in a liquid form, give the casting a thorough brushing with a new shoe brush; this will spread the wax uniformly over the entire surface and at the same time remove all the surplus wax. Then allow the casting to cool, and, with a second shoe brush, give it a thorough brushing, and you will have a surface to your pattern that will give you a mold with as sharp corners as your pattern.

THE HAIR OF SQUIRRELS' TAILS FOR BRUSHES.—A useful hint in regard to the utilization of squirrels' tails is contained in the *Chicago Field*, in the form of an extract of a letter written by Mills Brothers, manufacturers of brushes in Brooklyn, N. Y. They state a fact, which is perhaps known to few of our readers, that the so-called camels' hair brushes are made from the hair of the tails of squirrels, the demand for which is increasing very rapidly. It is a question, however, whether the tails of the California squirrels—animals extremely destructive to the crops in this State—will answer the purpose, as they are not true squirrels, but a *spermophile*, or ground squirrel. The hairs on the tail of this animal, although long, are coarser than those of the tree squirrel, and probably less desirable. There would, however, be no difficulty in obtaining a sufficient supply of the tree squirrels, such as the red, the gray, the fox squirrel, etc., throughout the various parts of the country, to meet a very large demand.

CHARCOAL IMPROVED BY AOE.—It is well known that mineral coal deteriorates rapidly by exposure to the atmosphere, through the loss of inflammable gases and the slow oxidation of its other constituents. But with charcoal the reverse is true. Charcoal improves with age by the mechanical absorption of oxygen, which does not combine with it until sufficient heat is applied to burn the coal, at which time the excess of oxygen adds intensity to the flame, and of course produces more heat than would be given off by the coal if burned immediately after being made.

TO DETECT LEAKS IN GAS PIPES.—Apply soapuds to a suspected leaky joint in the gas pipe. The formation of bubbles will show any escape. This is safer than trying the joint with a lighted match. If the leak occur in the branch of a bracket or chandelier, it is repaired by soldering with plumber's fine solder; if it be a very small one, heat the place first with a spirit lamp, and fill the aperture with cement.

TO DETERMINE THE SIZE OF GAS PIPE NEEDED.—Following is the London rule for gas pipe sizes: For 200 lights, two inch iron tube; 120 lights, one and one-half inch; 70 lights, one and one-fourth inch; 50 lights, one inch; 25 lights, three-fourth inch; 12 lights, one-half inch; 6 lights, three-eighth inch, 2 lights, one-fourth inch.

TO FASTEN LABELS TO TIN CANS.—Put a teaspoonful of brown sugar into a quart of paste, and it will fasten labels as securely to tin cans as to wood. Housewives may save themselves much annoyance in the loss of labels from their fruit cans when putting up their own fruit, by remembering this fact.

It is said that one pound of gold may be drawn into a wire that would extend round the world.

TO COAT NAILS WITH TIN.—It often becomes desirable to coat nails with tin when used for certain purposes, as for picture hanging, etc. This may readily be done by any purpose in a very inexpensive and simple manner, as follows: Put half an ounce of powdered tin (which may be procured of any operative chemist) into a common Florence flask; pour on about two ounces of concentrated muriatic acid, and boil over a spirit lamp until the tin is dissolved. When cool, pour into any convenient vessel, and dilute with about an equal bulk of pure water. Drop in the nails required to be coated, holding the vessel so they may all fall to one side. Immerse a piece of sheet copper into the solution, as far apart from the nails as possible, and connect it with the latter by means of a piece of copper wire. The effect of this arrangement is the development of a voltaic electricity, which causes a rapid decomposition of the fluid, and the deposition of tin on the surface of the nails. After being subjected to this treatment for about an hour, the nails will be found to have received a thick coating of metal, and may then be removed from the liquid, dried and polished. Steel pens may be coated in the same manner—a process which effectually prevents their rusting. They may be coated entire or merely the nibs may be subjected to the operation.

HOW TO BUILD A LIME KILN.—Patrick Egau, of Cheshire, Conn., who has had much experience in that direction, sends the N. Y. *World* the following in regard to building lime kilns: Do not use freestone, but build of pure limestone; no matter if they are three or seven feet long, put them all endways across the wall; then every time the kiln is burned three or four inches of the kiln will burn off as good lime as any in the kiln. Sandstone will color the lime and spoil it for perfect use. Build only one foot wide in the bottom for 16 inches high; then let it run wide when about six or seven feet high; it will be 10 feet wide and 13 long; then it is brought in again to about 9 by 11 on the top. The narrow place at the bottom is for a grate, where the ashes can be removed each morning. The grate is made of limestone, placed about three inches apart; over this is an arch for the wood two feet and six inches high. It will take from six to eight days to burn from two to three hundred barrels. This correspondent always burns with peat.

STEEL AND IRON WIRE ROPE.—Round steel wire rope will bear more than double the weight required to break iron wire rope of similar diameter.

GOOD HEALTH.

Care of the Hands.

Great care should be taken to keep the nails neat and well trimmed. They should be rounded at the top, and not too closely. Their polish and rosiness may be increased by brushing and rubbing.

To improve the skin of the hands and arms, take two ounces of Venice soap, and dissolve it in two ounces of lemon juice. Add one ounce of the oil of bitter almonds, and a like quantity of oil of tartar. Mix the whole, and stir it well until it has acquired the consistency of soap, and use it as such for the hands.

The paste of sweet almonds, which contains an oil fit for keeping the skin soft and elastic, and removing indurations, may be beneficially applied to the hands and arms.

For hands that are stained, there is an easy remedy. Dampen the hands first in water, then rub them with tartaric acid, or salt of lemons, as you would with soap; rinse them and rub them dry. Tartaric acid, or salt of lemons, will quickly remove stains from white muslin or lins. Put less than half a tablespoonful of salt or acid into a tablespoonful of water; wet the stain with it, and lay it in the sun for an hour; wet it once or twice with cold water during the time; if this does not remove it repeat the acid water, and lay it in the sun.

A most excellent ointment for hands that are scratched, burnt or sore, is thus prepared: Take three drachms of camphor gum, three of white beeswax, three of spermaceti, two ounces of olive oil—put them together in a cup upon the stove, where they will melt slowly and form a white ointment in a few minutes. If the hands be affected, anoint them on going to bed, and put on a pair of gloves. A day or two will suffice to heal them.

For chapped hands, instead of washing the hands with soap, employ oatmeal, and after each washing take a little dry oatmeal and rub over the hands, so as to absorb any moisture.

—*Illustrated Weekly.*

TREATMENT OF BEE STINGS.—A writer in the *American Journal of Microscopy* gives the following directions for the treatment of a bee sting, which are worth remembering: "Onions, ammonia, ashes, beef and a hundred other remedies have been prescribed, but we never found them of any special value. If the poison-bag has not been emptied, remove it with a sharp knife, or still better, with a pair of tweezers, so formed as to grasp the sting itself without pressing on the bag. Common hair tweezers are just the thing. This must, however, be done very quickly, or it will be of no use. Grasping the bag and sting with the fingers only squeezes the poison out of the bag and into the wound. After the bag has been removed suck the wound strongly and apply a poultice of moist mud. We have never found anything better."

Breathing Through the Nose.

There are various reasons for considering the nose the natural outlet of the lungs, and hence various advantages to be derived from breathing through the nose.

1st. If we breathe through the nose we will be enabled often to detect the presence of noxious odors in the air we breathe, and so be warned of danger in time to prevent it.

2d. The internal nose is studded with hairs, which in some degree at least prevent the ingress of noxious matters with the air we breathe. Dust is strained out, and it is confidently asserted by persons who have tested the matter, that miasmas are prevented from entering the blood if one breathes only through the nose. Some persons have lived in malarious districts, slept on the banks of malarious rivers, etc., for years, and yet have escaped all the forms of fever which usually followed a residence in the country, who have ascribed their exemption solely to the settled habit of breathing only through the nose.

3d. By breathing through the nose, little, if any, air passes into the lungs until it has come in contact with the membranes of the nose, which are supposed to possess some power of neutralizing malarious and contagious poisons.

4th. By drawing our breath only through the nose, the air is warmed by contact with the membranes before it reaches the lungs, and so inflammations and congestions of those organs are avoided.

Per contra, the habit, so common, of breathing through the mouth has many disadvantages. In this way a great volume of air is quickly taken in, loaded with dust, malarious or contagious impurities, etc., of which we are utterly unconscious, until the blood has been poisoned, and serious and perhaps fatal disease been inaugurated. The cold air being taken in in great volume and with great rapidity, chills the lungs, whereas, if breathed through the nose, it would be warmed before reaching the lungs.

The habit of breathing through the mouth is caused largely by weakness of respiratory muscles, and one excellent method of strengthening those muscles is to breathe through the nose. It is certainly as wise a plan as sucking air through a silver tube, so often recommended. Then breathe through the nose, as nature indicates, if you would have good health.

Eating—How to Keep off Dyspepsia.

It is an old German adage that "more people dig their own graves with their teeth than with spades," and verily it would seem so if we would look at the immense number of dyspeptics, rheumatics and gouty individuals, creeping through life in pain and wretchedness. Yet it is next to impossible to induce even thinking people to control their appetites, and to eat such things and at such times as nature shows them to be necessary and right. Dr. Hall declares, unhesitatingly, that it is wrong to eat without an appetite, for it shows there is no gastric juice in the stomach, and that nature does not need food; and not needing it, there being no fluid to receive and act upon it, it remains there only to putrefy, the very thought of which should be sufficient to deter any man from eating without an appetite the remainder of his life. If a tonic is taken to whet the appetite, it is a mistaken course, for its only result is to cause one to eat more when already an amount has been eaten beyond what the gastric juice is able to prepare. The object to be obtained is a larger supply of food; and whatever fails to accomplish that essential object, fails to have any efficacy towards the cure of dyspeptic diseases. The formation of gastric juice is directly proportioned to the wear and tear of the system, which it is to be the means of supplying, and this wear and tear can only take place as the result of exercise. The efficient remedy for dyspepsia is work—out-door work—beneficial and successful in direct proportion as it is agreeable, interesting and profitable. —*National Granger.*

Don't Worry Yourself.

To regain or recover health, persons should be relieved from all anxiety concerning diseases. The mind has power over the body. For a person to think he has a disease will often produce that disease. This we see effected when the mind is intensely concentrated upon the disease of another. It is found in the hospitals that surgeons and physicians who make a specialty of certain diseases are liable to die of them; and the mental power is so great that sometimes people die of diseases which they only have in imagination. We have seen a person seasick in anticipation of a voyage before reaching the vessel. We have known a person to die of cancer in the stomach when he had no cancer or any other mortal disease. A blindfolded man, slightly pricked in the arm, has fainted and died from believing that he was bleeding to death. Therefore, well persons, to remain well, should be cheerful and happy; and sick persons should have their attention drawn as much as possible from themselves. It is by their faith that men are saved, and it is by their faith that men die. If he wills not to die, he can often live in spite of disease; and if he has little or no attachment to life, he will slip away as easily as a child will fall asleep. Men live by their souls, and not by their bodies. Their bodies have no life of themselves; they are only resources of life—tenements of their souls. The will has much to do in continuing the physical occupancy or giving it up.

DOMESTIC ECONOMY.

How to Breakfast.

The *Sanitary Record* (English) sneezes our American custom of a substantial meal soon after rising, as follows: Let a healthy man really "break" his "fast" with a substantial meal, and not break his breakfast with irritating little nips or slops beforehand. After the stomach has at its leisure emptied itself during sleep of its contents, and sent them to repair the worn tissues and exhausted nerve force, and the blood has been ventilated and purified by washing and dressing with the window open, then is the time when the most perfect of all nutritive articles, farinaceous food, can be consumed in larger quantities with advantage. Butter also, and fat and sugar, troublesome customers to weak digestions, are then easily coped with, and contribute their invaluable aid to performing the duties of the day. For example, many persons can drink milk to a fair and useful amount at breakfast, with whom it disagrees at other hours. And the widely advertised "breakfast bacon" by its name warns the consumer against indulgence later on in the day. *Cafe au lait* and sweet, creamy tea are to many men poisonous in the afternoon, though in the prime of the morning they are a wholesome beverage to the same individuals. Let the vigor, good humor, and refreshment then felt by a healthy man be utilized without delay in eating a hearty meal immediately after he is dressed, and not frittered away in the frivolities of other occupations. Let not reading, writing or business—muscular, political or economical—exhaust the nervous system. The newspapers and letters should not be opened, preferably not delivered, till the appetite is thoroughly appeased.

Economy in Housekeeping.

In buying anything, be it groceries or cotton cloth, be not "penny wise or pound foolish." Some people with an honest desire to economize look well to the "spigot but forget to watch the bung." They spend hours running from one store to another to see where they can buy the cheapest, and if they get an article a few cents less at one place than has been asked them at another, they are in high spirits over their purchasing ability, never dreaming that they have, even at the price given, paid more than the article was worth! Some cannot discriminate fine flavored coffees from that of insipid or rank flavor. That being the case, a cheap article will answer their purpose just as well. Indeed many people educate their taste just to suit their purse—that is well. A man with a shun purse is better pleased and much happier if he have not a refined taste, as it is certainly an expensive thing to own; but if he have, better buy a little of a good article than a good deal of a poor one.

Nothing is ever gained by buying cheap articles, nor by changing your place of trade often. Trade at one place year after year if you can find a place to suit you. A store keeper soon learns to prize you if you prove a good cash customer, and will give you many liberal trades. I have known them many a time to even tell a good customer when there was going to be a rise in a certain article, and advise the purchasing of more than the usual stock. Transient customers never reap the benefit of any such hints, and then wonder why they cannot buy things reasonably. —*Germantown Telegraph.*

TIPSY CAKE.—Take a stale sponge cake, cut the bottom of it so as to make it stand even on a glass dish. Make numerous incisions in it with a knife, and pour over it half a pint of sherry and a glass of brandy; let the cake soak these all up. Blanch, peel, and slice some sweet almonds, and stick the cake all over with them. Blanch, chop, and pound in a mortar one-quarter pound of sweet almonds, moistening with a little orange flower water to prevent their oiling; add one pint of milk and the yolks of six eggs; sweeten to taste with powdered loaf sugar. Stir over the fire till the custard thickens, but do not let it boil. Keep stirring now and then till it is quite cold, then pour it round the cake. Garnish the dish with crystallized fruit, and it is ready.

EGGS AND MINCED VEAL.—The N. Y. *Times'* recipe for preparing eggs and veal is the following: Take some remnants of roast veal, trim off all browned parts, and mince it very finely; fry a shallot, chopped small, in plenty of butter; when it is a light straw color, add a large pinch of flour and a little stock; then the minced meat, with chopped parsley, pepper, salt, and nutmeg to taste; mix well, add more stock if necessary, and let the mince get gradually hot by the side of the fire; lastly add a few drops of lemon juice. Serve with sippets of bread fried in butter, round, and poached eggs on the top.

FRIED CAULIFLOWER.—Pick out all the green leaves from a cauliflower and cut off the stock close. Put it head downward into a saucpan full of boiling, salted water. Do not overboil it. Drain it on a sieve, pick it out into small sprigs, and place them into a deep dish with plenty of vinegar, whole pepper, salt and a few cloves. When they have laid about an hour in this, drain them, dip them in batter, and fry in hot lard to a golden color.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

Subscriptions payable in advance.—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collection and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, March 4, 1876

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Bonanza Mines; The Bigelow Engine; The Fryer Process, 145. An Iron Furnace for California; Our Engineering Department; The Dilatation and Expansion of Liquids; Bulletins of the Government Territorial Surveys; A Divining Rod Expert, 152. Seymour's Cotton Planter, 153. Patents and Inventions; Notices of Recent Patents; Notice to Proprietors of British Patents; Inspecting Steam Boilers, 156. New Books, 157.

ILLUSTRATIONS.—The Bigelow Portable Engine and Boiler, 145. Seymour's Cotton Planter, 153.

MECHANICAL PROGRESS.—A New Form of Iron Furnaces; New Fuels; Carriage Wheels and What They Can Carry; Motive Power from a Permanent Magnet (?); Bessemer and its Uses, 147.

SCIENTIFIC PROGRESS.—Prof. Tyndall on "Germes"; What is Life; Reconstructing and Photographing Sound; A New Classification of Elements; Solar Protuberances, 147.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 148.

MINING SUMMARY from various counties in California, Nevada, Arizona, Colorado, Idaho and Montana, 149-154.

THE ENGINEER.—The Genesis of Architecture and Engineering; A New Scheme for Crossing the Mersey; Heating of Journals; Railways at the Bottom of the Sea; Reservoirs for the Mississippi, 150.

USEFUL INFORMATION.—Refrigerating Railroad Cars; Casting Stove Plates; The Hair of Squirrels' Tails for Brushes; Charcoal Improved by Age; To Detect Leaks in Gas Pipes; To Determine the Size of Gas Pipe Needed; To Fasten Labels to Tin Cans; To Coat Nails with Tin; How to Build a Lime Kiln, 151.

GOOD HEALTH.—Care of the Hands; Treatment of Bee Stings; Breathing Through the Nose; Eating—How to Keep off Dyspepsia; Don't Worry Yourself, 151.

DOMESTIC ECONOMY.—How to Breakfast; Economy in Housekeeping; Topsy Cake; Eggs and Minced Veal; Fried Cauliflower, 151.

CORRESPONDENCE.—Gems and Precious Stones; Card from Mr. Fryer, 153.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs on 157 and other pages. MISCELLANEOUS ARTICLES.—Thoughts on "The Million of the Press"; Jersey Mining District; White Pine Mines; An Expert's Estimate of the Bonanza; A Bird Hatched out from an Artificial Egg (?); The Black Hills, 146. The Santa Rita Placers; Consumption of Lead, 150. The Oso Mines; A Miners' Clothes Room; The Imperial Consolidated, 154. The Northwest Silver Mill, 156.

NEW ADVERTISEMENTS.

Mining Machinery Depot, Parke & Lacy, S. F.; Enamelled Steel Barbed Fence Wire, Jones & Co. Sacramento; Wood Working Machinery, Bentel, Margedant & Co., Hamilton, Ohio; Hoadley Engines, Treadwell & Co., S. F.

THE EMMA mine business is being investigated by the committee on Foreign Affairs of Congress, Minister Schenck's connection with the business bringing it within their jurisdiction. So far, some very damaging testimony has been deduced, but Senator Stewart and Minister Schenck have neither of them yet put in their replies. They propose to answer in person shortly. The worst feature of it all is the testimony against one man well known in scientific circles, who is represented as having received a large sum for his favorable report on the mine. The whole business is a bad one, and reflects discredit on the American name—the guilty parties being men of prominence and wealth.

BOILER INSPECTOR.—We give in another column Pullen's bill on steam boiler inspection. We understand that the author of the bill and the San Francisco delegation wish for an expression of opinion from this city. We should be glad to publish the views of any of our readers who are posted on the subject, who have anything to say for or against the bill.

An Iron Furnace for California.

At last California is to have her first iron furnace. This, which is usually the first manufacturing enterprise of a new country where the material is found, seems to be almost the last to have started here. The reason of this is doubtless the greater attraction which the precious metals have had for the capital and energy of the State. The enterprise of Mr. P. Fitzhugh, an experienced iron master, has at length drawn attention to this source of wealth, and capital necessary to assure the completion of the works during the coming summer has been secured. The furnace will be built near Clipper Gap, on this line of the Central Pacific railroad, where a fine quality of magnetic iron ore is found in great abundance, and where also all other materials needed in the manufacture of charcoal pig iron are easily and cheaply accessible.

There is up to this time no iron furnace west of the Rocky mountains—except ones in Oregon—and all of our iron is consequently imported. Mr. Fitzhugh thinks that he has found a place that far exceeds any in the United States for making pig, bloomed and rolled iron of the best quality at the least cost anywhere known to him, and with cheaper transportation to market than any other iron beds in California.

The cost of making one ton of pig iron at the locality named is computed at \$20, as follows: Mining and delivering two tons of ore, to make one ton of iron, \$3; mining and delivering limestone (which costs the Portland, Oregon, furnace \$5), 25 cents; superintending and labor, \$3.75; charcoal, 125 bushels at 10 cents (many furnaces only take about 100 bushels, and it is delivered to the Oregon furnace for nine cents), \$12.50; repairs on furnace, making about 5,000 tons, \$2,500 per year (or per ton) 50 cents; total, \$20 per ton. The transportation from furnace to San Francisco is \$3.66 per ton, so the cost of working and delivering one ton of pig iron in this city is estimated as above at \$23.66.

According to analysis by Professor Price, of this city, this magnetic iron ore contains 62.44 per cent. of iron, and has no injurious ingredients that would in any way affect the quality of iron. The iron ore and limestone beds are large, rise nearly to the surface and can be quarried and delivered much cheaper than the cost to New York or Oregon furnaces, and the latter have to drift many feet under ground and transport their ores or limestone hundreds of miles. The ores are in the vicinity of an immense growth of wood, which can be easily and cheaply conveyed to the proposed furnace, and can be reduced to charcoal at any season of the year, and do not require to be collected in large quantities for winter supplies. It is stated that the ore will work the toughest iron, suitable for car wheels and steel rails. Professor Whitney, late State Geologist of California, in Vol. I., page 884 of his report, gives an account of the deposits of iron ore within six miles of Auburn, Placer county (the place in question), and says:

"It is in larger quantity than has yet been discovered in the auriferous slate series, cropping out on a side hill and forming a mass of more than thirty feet thick, of which the longitudinal extent is not known, although it is evidently considerable. It is hematite, appears to be of excellent quality and remarkably pure and free from intermixture with rocks. This locality is more favorably situated than any yet discovered in the State."

We understand that the amount of capital required in the business of starting this furnace for the first year is about \$75,000, and that all the arrangements have been perfected. We are very glad to know that at last California is to have an iron furnace and hope it will not long be the only one. The population of the State has increased so materially, and the demand for iron for various purposes is so great, that it is a pity to see so much money going out of California which could be saved within its borders and at the same time develop a new and profitable industry, both for capitalists and laboring men.

Our Engineering Department.

We commence in this week's issue of the Press a department of "Engineering," which we propose to continue and to make as interesting as possible for our readers. The term "Engineering" includes a multitude of subjects, all of them of broad scope, and we shall endeavor to obtain as much local matter as possible of every variety connected with the subject. To do this we need the co-operation of engineers and others interested, and urge those who have anything of interest to communicate, not to neglect to forward it to us for publication.

In mechanical engineering particularly, there are many among us well posted, who could furnish matter of great value, not only here, but elsewhere. We trust that they will aid us in making this department of local interest to engineers generally. If those who do not think they have time to write will simply suggest to us proper sources of information, we will hunt up all the details willingly. Although our people are all very busy during business hours, a

half hour in the evening occasionally will afford an opportunity of writing out whatever they have seen and interesting in this connection. We shall endeavor to make our Engineering Department take as much of a local character as possible, and to this end solicit contributions on any subjects connected with it.

The Dilatation and Expansion of Liquids.

Scientific Lecture by Father Neri.

Rev. Father Neri delivered the second of his course of scientific lectures for the present season at St. Ignatius college, on Tuesday evening last, on "The Dilatation and Expansion of Liquids by the Application of Heat." The Rev. Father, in his opening remarks, made a brief reference to the subject of his first lecture on "The Dilatation and Expansion of Solids," showing that the same cause produced the same effect on both solids and fluids, only in a greater degree on fluids, from the fact that they were more sensitive. This difference of sensitiveness grows out of the different molecular forces existent in the two classes of bodies.

In solids the attraction of cohesion is the governing force, repulsion being scarcely felt; while in fluids neither cohesion nor repulsion has any advantage, the molecules being perfectly free to move or expand. Still all liquids do not expand alike; for while one volume of water, advanced in temperature from 0 to 100° C., increases one-twenty-second in volume, mercury increases during the same advance in temperature one-fiftieth of its volume, alcohol one-ninth, the fixed oils one-twelfth, and ether and turpentine each one-fourteenth.

This varied expansion of liquids was shown by plunging into hot water flasks of various fluids, with tubes attached. The fluids were so colored as to make the elevation of the water therein, due to expansion in the flasks, perfectly visible to the entire audience.

A Disturbing Element.

The lecturer here called attention to the fact of a disturbing element inseparable from all such experiments in the expansion of the containing vessels as well as the fluids. That such was the fact to a very appreciable degree was beautifully shown by placing the tube connected with the flask, when in the act of applying the heat, in the path of an electric beam of light projected through a lens upon a screen, whereby the shadow of the movement of the liquid in the tube was greatly magnified. By that means it was plainly observable that a fall of the fluid occurred in the tube when the flask was first placed in the hot bath, due to the expansion of the glass before the heat was communicated to the fluid contained therein. This experiment was a very beautiful and most satisfactory one.

The Linear Expansion of Glass.

Was also shown by exposing to heat a glass rod having metallic caps on each end, so that its expansion was caused to close an electric circuit, by which a platinum coil, placed in an exhausted receiver, was made to glow with a red heat, and an electric bell to sound a note of alarm. The principle and effectiveness of the electric fire alarm was also beautifully illustrated by the employment of a column of quicksilver to form part of an electric circuit.

Several Other Interesting Experiments

Were made to show the expansibility of glass. The principle of the Bologna flask and Prince Rupert drops was also shown and explained; and the large amount of force generated in the explosion of the latter was demonstrated by exploding one of the drops in a glass vessel filled with water. The vessel was shattered to pieces, and the water scattered in every direction.

The Enormous Power

Due to the expansion of water was illustrated and dwelt upon at considerable length. The learned lecturer assured his audience that it would be easier to drive a nail into a block of steel than into a body of water subjected to great pressure, and so confined that no portion of it could escape. A power of 20,000 pounds to the square inch can readily be obtained from the application of a few degrees of heat to a vessel of water absolutely tight and able to sustain such an enormous power. The lecturer showed a large bombshell and a heavy quicksilver flask, both of which had been fractured by filling them with water and submitting them to a slight increase of heat. A power of enormous value, produced at a very slight expenditure of heat, may be generated in this manner. Although the movement must be slight, owing to its great force, it may be largely multiplied and possibly utilized in a practical manner. There may be great possibilities in this direction for future generations to work out. It is a subject worthy of the admiration and study of all. The lecturer remarked that we had heard much of late about

The "Keeley Motor."

Which was to revolutionize the application of power. No boiler, no heat, no expense, but yet an unlimited amount of power readily convertible to practical use. The secret could not exist in the dilatation of water, for that requires heat, and fully recognizes the correlation of forces, while Keeley utterly ignores all the established principles of science. The grand error on which so many excellent mechanics become wrecked, is the endeavor to create power.

The third lecture of the series will be delivered April 27th, the last Thursday of the month.

Bulletins of the Government Territorial Surveys.

The work done in the United States geological and geographical survey of the Territories, under Professor Hayden, is of great value and importance, notwithstanding the assertions to the contrary of persons who can see nothing but a "job" in everything undertaken by the government. A survey of this character can not, of course, do such accurate work as a coast survey, which goes over ground slowly and carefully and measures every inch. The Territorial surveys are only intended to be preliminary and general in their character, and so great is the extent of country which they are expected to cover, that prominent features only can be noticed and accurate detail left for future investigation after the ground work is finished. The publications of the survey are exceedingly valuable, giving correct ideas of the almost unknown localities which they describe, together with such scientific facts and deductions as are considered of utility. The corps of scientific men employed is not large, but their opportunities are such that they are able to publish a great deal of new matter more particularly valuable to scientists.

The publications of the survey comprise annual reports and bulletins, the latter containing more technical information than the former, which are of a general descriptive character. The Bulletin of the Survey was commenced in 1874, for the purpose of giving to the world more rapidly than through the annual reports the vast amount of new material which was constantly accumulating under the auspices of the survey, and in most instances demanding prompt publication. When the first and second numbers were printed it was not expected that it would continue long or be issued with any regularity; but its success was so great that it commenced the year 1875 as a regular serial, and six numbers have been issued of about 500 closely printed octavo pages, with 26 pages of maps, sections and other illustrations, with table of contents and full index. The table of contents has been prepared so that the numbers for 1874 and 1875 can be bound as Vol. I. During the year of 1876 the Bulletin will be continued. Most of the articles in the Bulletin will not be reprinted, especially the more technical ones; but those of a popular character will appear again in the annual reports, usually much enlarged and improved. The numbers already issued and distributed ought to be preserved, as several of them are out of print and will not be reissued.

A Divining Rod Expert.

A complaint has been filed in the Third District Court by A. Peck, against Michael Castle, in which he charges that, in 1872, he and Castle entered into a contract, whereby Castle agreed to pay his expenses to and from Virginia City, for the purpose of pointing out to P. Deidesheimer, at that time superintendent of the Ophir mine, where the ore body of said mine lay; and that if the ore body should be found after nine months of regular work in the course that Peck would point out as the course of said ore body, then he, Castle, would deliver to Peck 100 shares of Ophir company's stock at the price of \$50 per share.

The document on which this suit is brought is a peculiar one, and is in the following words: "San Francisco, March 2d, 1872—Michael Castle, on behalf of a party of gentlemen owning a quantity of Ophir company's stock, and having power to act for them, agrees with Mr. Peck to pay his expenses to and from Virginia City, for the purpose of indicating to the superintendent, P. Deidesheimer, where he asserts there is a body of ore. Should it prove, by future working in the direction Mr. Peck indicates, and when the work is done that may develop it, even only to show it is there, I, on behalf of the aforesaid gentlemen, and on my own security and distinct fulfillment of this agreement, will deliver Mr. Peck 100 shares of Ophir company's stock, at the price of \$50 per share, at his option, within nine months from this date. MICHAEL CASTLE."

Witness: A. H. Liska, Jr.

Peck, the plaintiff, alleges that he did go to Virginia City and point out to Deidesheimer the locality of the ore body, and that the work was for a time carried on as he directed it should be. But, he says, this was done for only a few months, and then the miners were taken from the proper course and made to work in another part of the mine, in violation of Castle's agreement with him.

The plaintiff then alleges that in the fall of 1874, the miners having been allowed to work in the course he had before marked out, the body of ore was discovered where he told Deidesheimer it would be; and that the new shares of stock advanced to and were worth on the market of San Francisco \$350 per share, making \$35,000 as the value of the one hundred old shares of stock he was entitled to have of Castle at \$50 per share. Therefore, he asks for \$20,000 in damages. "Professor" Peck is well known in Nevada, and considers himself an expert in pointing out ore bodies by the aid of the "divining rod," but whether he located the ore body referred to by this means, we do not know.

HOISTING machinery for sinking the new shaft of the Leo mine, on the Comstock, has already been ordered, and will be on the ground, ready for erection, in a very few days more.

Gems and Precious Stones.

(Written for the Press by HENRY G. HAWKS.)

(Continued from last week.)

The hydrostatic balance in use formerly was furnished with an extra pan with short supporting wire; a hook on the under side of the short pan served to support the specimen while it was being weighed in water; but an ingenious modern contrivance does away with the necessity of the short pan. Take any ordinary balance, the pans of which hang from the ends of a beam. Make a little stool, like a common bench, the legs being just far enough apart to allow the pan to rise and fall without touching them; the top of the bench must be at least an inch and a half wide. It must be placed across the left-hand pan and at right angles with its wire supports. The bench must be as low as possible to admit of the placing upon it a suitable vessel to hold water for the second weighing—as will be described. The vessel must be large enough to allow the specimen to hang in it without touching by at least half an inch on either side; a small ring is attached to the same hook which supports the pan, a very fine wire will also be required, which may be made of copper, or better, of platinum. This wire must be as fine as possible and each end bent into the form of a hook, a fine thread of silk or a horse-hair may be used instead of the wire; but they will be found more difficult to manage. When all is ready the little bench is placed in position and the vessel to contain this water is placed empty upon it. One end of the wire is passed around the specimen and hooked. The other end is hooked into the ring at the end of the beam. If all has been properly arranged, the specimen will hang from the beam into the empty vessel without touching it. Weights are then placed in the other pan until the beam is in equipoise. These represent the weight of the specimen in the air. A memorandum of the weight is made, and distilled water is poured gradually into the vessel until all parts of the specimen are covered. Some little time must be allowed to elapse before the second weighing is made. This is to give time for air bubbles to form, in which case the specimen must be removed from the water and its surface touched gently with a soft brush. When it is replaced in the water no more bubbles will appear, and the operator may at once proceed with the second weighing. The specimen will be found to weigh less than it did in the air. The second weight is noted, and from the data so obtained the specific gravity may be calculated.

The weight of the specimen in water must be subtracted from its weight in air, which will give the loss or the weight of an equal volume of water, and by dividing the weight in air by this loss, the specific gravity is ascertained.

An example will furnish the best illustration:

Suppose the weight in air to be 40.36 grms.
" " " " water " 27.08

Loss, or equal volume of water, 13.28
Then—
40.36
— 13.28
— = 3.039 specific gravity.

Another method of determining specific gravity and of great use to gem hunters, is the "specific gravity bottle." But its use necessitates the having distilled water and a very sensitive balance. More than one of these bottles will be required. Small stones must be weighed in small bottles and vice versa. Suppose a case: Let it be required to determine the specific gravity of a stone the size of a pea. A bottle with a sufficiently large mouth and holding the least quantity of water to cover the specimen should be selected. The bottles must be chosen with great care. They should be provided with glass stoppers, rather long and well fitted to the neck. In all cases the stoppers must be weighed with the bottles. The bottles should be without flaws, and should be specially examined on the bottom to see if that part which is attached to the tube in blowing is smooth, and that small fragments of the glass are not likely to be broken in using, in which case the weight of the bottle would be less unexpectedly, which would lead to mistakes. With a sharp file, a little channel must be cut lengthwise of the stopper, to allow any superfluous water to escape when the stopper is placed in the mouth of the bottle brim full.

A counterpoise must be made the exact weight of the bottle. Before this is adjusted the bottle must be wiped dry and clean both outside and inside. The counterpoises may be made of lead, hammered into a cube; when nearly correct, place the clean and dry bottle in one pan of the balance and the counterpoise in the other, then by scraping with a knife remove the excess of metal until the weight exactly corresponds with that of the bottle. Then reverse them, that is, change the weight to the pan which before held the bottle and the bottle of the other. If they still seem to be correct, the balance is in adjustment, and you may expect correct results. If not, care must be taken always to weigh the bottle in the same pan, by which precaution nearly all the errors of the balance may be avoided. When all is

ready return the bottle and counterpoise to the proper pence and see if they again balance each other; remove the bottle, fill it full of distilled water, replace the stopper, carefully pushing it down hard, wipe it dry with a clean cloth, and examine it to see if it is full of water, and that there are no air bubbles around the stopper; now put weights in the pan with the counterpoise until the beam is again in equipoise; write down the weight of the water and mark it "A." Pour out the water, wipe the bottle dry and clean inside and outside, and again place it in the same pan of the balance, drop in the stone and weigh again; mark this quantity "B."

(To be Continued.)

Seymour's Cotton Planter.

We print on this page this week an illustration of an improved cotton planter, invented by Pierpont Seymour, of East Bloomfield, Ontario county, New York. It is the result of many experiments in testing various devices for distributing cotton seed (and also fertilizers) by machinery. It is claimed that its action upon cotton seed, is such that it will distribute the seed so as to secure a continuous discharge from the hopper into the ground, in the same manner as a good grain drill will distribute wheat and oats. Should it be desirable to moisten the seed and mix it with fertilizers, it will in no wise hinder the operation. The

SEYMOUR'S COTTON PLANTER.

machine may be made broad enough to plant three rows at a time, and yet not be too heavy for one horse, and when made to plant but two it is light work. It plants the rows three, three and a half or four feet apart, and may be so made as to plant them any desired distance. The teeth for planting action are easily removed, and as many cultivator teeth substituted as to fill the entire space between the teeth, thus converting the machine into a very desirable and efficient cultivator. These teeth are especially adapted to this machine, and attached to the "drag bars" in the same manner as the teeth for planting. They set in double rank to prevent clogging, and can be so ganged as to run shallow and just shave the top of the ground, or to penetrate to a depth of six inches. When deep cultivating is required, a pole is used for two horses, and by removing the two middle teeth, two horses may be used to cultivate young cotton or corn, by straddling the row; and when one horse is used for this purpose, the two outside teeth should be removed. Whether planting or cultivating, the whole is under the entire control of the driver as he sits in the seat.

The whole of last week was expended on the Hale & Norcross mine in hoisting and pumping water, with no visible effect toward a reduction of the body on the lower levels of the mine.

A WORKMAN in the Washington mine at Hornitos, named Williams, was hanged under twenty-five feet of earth by a cave last week, and at last accounts his body had not been recovered.

The San Jose woolen mills have still so large a stock of goods on hand that it has been determined not to resume operations at present. The mills have been closed two months.

Card from Mr. Fryer.

EDITORS PRESS:—I feel in duty bound to respond to some of the recent attacks upon the Fryer process, though it is better to avoid, generally, any contest with persons not governed by gentlemanly principles, especially if such persons have little or no knowledge of the subject they attempt to discuss.

Rossiter W. Raymond, author of the articles in regard to this process which have been so generally quoted here and elsewhere, is as far a sample of this class of persons as I ever had the misfortune to meet while innocently progressing with a mechanical or chemical subject.

In the article in the *Mining and Engineering Journal* of January 15th, he shows the qualities of an unfair pugilist who strikes an unguarded person and then challenges him to fight. Mr. Raymond first attacked my preliminary process with ridicule, criticized the business management of the company, sneered at local accounts of my success, and then wound up by saying, "I pause for a reply."

It was not necessary for me to reply. A hundred ready pens would have contradicted his statements, had I allowed it. As it is, a few items appear to satisfy the public that I am not a common liar or swindler. In answer to all such items, Mr. Raymond simply asserts

men, work to their satisfaction like the fruit of my humble endeavors has, and you will not find me at your back with a dagger, but faithfully rendering you every assistance—not for your personal benefit, but for the sake of our impoverished country.

Mr. Raymond says: "Processes heralded with glowing but mysterious announcements, as revolutionizing the art of metallurgy, are usually swindles. Mr. Fryer's enterprise having been unfortunately attended with some of these features, we took pains to say that we did not rank it in that class." For this I am thankful, and regret that Mr. Raymond had not given me notice before publishing his first criticism. I would have been as open with him on this subject as with any gentleman here who has been taken into my confidence. Then, if he had chosen to condemn the process, we would at least have been evenly balanced as regards knowledge thereof. But returning to the above quotation, I would inform Mr. Raymond that the publicity given to the Fryer process is due to the press itself, and was unsolicited by me. I appeal to every editor in this State, or in the United States, to answer if I have ever asked one of them to publish anything in favor of my process until after it had gained a wonderful newspaper notoriety, when I wrote some cards over my own signature to correct erroneous descriptions, and also to quiet the excited people who were bent upon returning to certain deserted districts to regain their fortunes where they had lost them, because my process had been reported capable of working ores once refractory. I could easily have ended the swindle here, had it been such, by a course too apparent to mention.

Some of the iron men in San Francisco, even before the issue of any part of my invention, declared that at an expense of \$1,500 they had procured copies of my case, and that it was a failure.

I know no reason for this unless it is because some of them have suffered through the fact that a great many mining men were waiting for me to furnish them with our kind of apparatus, while on the contrary I have advised nearly everybody who had properly not to wait for me; that they could perhaps build a mill and pay for it before we were ready to supply them. Again, Mr. Raymond refers to an assay made at Virginia City of a piece of bullion produced by our process. I can only answer that I know not its contents or character until after the assay was made. The amount of the ore tested was 18 pounds as stated, for the reason that the gentleman who brought the ore had no more of the same character. But here let it be understood that some of our charges amount to four tons, and the more of them that we run, the more regular works the apparatus. Now, in regard to the purity of bullion produced, especially silver, he it understood that I do not allow every result above 900 fine, though in many cases such it is.

I have been censured for not issuing my patents more rapidly, that people may have a chance to criticize the claims thereof. There would be no objection to this, were it not for the reason that such patents would be as apt to fall into the hands of unprincipled novices, who, when finding something that is not laid down in books, preclaim: "We have found something wrong, or else we don't understand it, therefore there must be some swindle about it." Now, as my patents on this account will be issued as slowly as possible, let me entreat everybody to withhold criticism until after the whole case is made public.

In this connection, though I will not be unkind enough to challenge Mr. Raymond to visit my works and find something in metallurgy which he has never before seen, I will say in all earnestness that should Mr. Raymond at any time visit this part of the country, I will open to him my works, and do all in my power to make his trip a pleasant one.

In conclusion, permit me to express my sincere thanks to the correspondent of your paper of the 26th ult., for his gentlemanly criticism of the Fryer process, which he was willing to stop at the point where his knowledge of the process ended. Whether right or wrong he shall one day have a chance to satisfy himself, as I wish it to be fully understood that I will, as soon as possible, invite everybody interested in these matters to visit these works. With this assurance, I remain,

Very respectfully yours,

ROBT. M. FRYER.

Grass Valley, March 1st, 1876.

In the South Comstock mine water has so increased that the mine is flooded like the Savage, and the machinery is totally incapable of reducing or managing it at all; consequently, work is suspended for the present, until the management shall decide what course to pursue.

The snow near Yreka is so deep that the roads are impassable, and travel has been entirely suspended in some directions.

MINERS are leaving Gold Hill and Virginia almost daily for the Black hills.

The Coso Mines.

A correspondent of the Kern County Courier gives his general impressions of the Darwin country as follows:

I have been in Darwin several weeks, a quiet looker on, never obtruding, nor suspiciously inquisitive, and have visited most all of the mines that are in successful operation, those being developed and those having but a name and an owner. Of those being worked and having furnaces producing bullion, I need not specially speak. I wish to enumerate, for the benefit of my friends, some of the mines not yet brought before the public. I will do Darwin district first. The Defiance, New Coso and Cuervo, each have furnaces in operation and are producing large quantities of bullion, the latter furnace, at this time, running a contract for the Coso Consolidated company, which company owns the Bella Union mine. The New Coso furnace is running on ore from the Christmas Gift and the Lucky Jim mines. I will now mention the Cuervo and Grand mines, on a line north of the Defiance, both giving promise of developing into good mines. Continuing north and a little west, is the Union, a mine with some fine looking ore on the dump. This mine is but a few hundred yards on a direct line with the Bella Union. About one mile from the Bella Union is the Independence mine, which shows well in a shaft now down to quite a depth. Just south of the Independence is the Blade mine, with a hole sunk on it sufficient to show a good body of mineral, which assays quite well for a surface prospect. The mines mentioned in the foregoing are located north of the town of Darwin. Going east of town I found, first, the Benham mine, one of the best defined locations in the district, having fine croppings, and from ore taken from the shaft sunk upon it good assays have been made. East of the Benham is the Falcon, undeveloped, but similar in appearance on the surface to the Benham. Farther east lies the Keystone, a mine developed sufficient to show good mineral. South of town, or rather southeast, lies the Norton mine, with a shaft sunk to a good depth and showing mineral in encouraging quantities. Further south is the Arambula, having on the dump quite a large pile of fine looking ore, owned by Mexicans. And continuing in a southeasterly direction I came to the Santa Rita, with a big hole in the ground and a large pile of ore on the dump, owned by Mexicans. This mine is destined to soon make a good report in our camp.

Leaving Coso district, (Darwin) I took a trip one day to Lookout district, 10 miles southeast of Darwin. In this district I visited the St. George, a gold bearing ledge, which contained fine free gold and sulphurets in almost every piece I broke from the croppings. This is a big mine—it can be traced by outcroppings for the distance of three or four claims, say 5,500 feet. Parallel with and just south of the St. George mine is the Lighthouse mine, having the general characteristics of the St. George, and fully as easily traced on the surface. On this ledge are several locations. Further east, and near the west side of Panamint valley, and on a line with the St. George, is the Ida mine, one of the best situated locations in that neighborhood, and gives promise of assaying as well as the St. George or Lighthouse. I looked at other locations in the neighborhood of the above mines, but did not get the names of them. That portion of Lookout district which I visited is a gold producing belt, being in granite formation—just such an appearing country as an old quartz hunter would look for to find gold bearing ledges. North of the claims mentioned here, in Lookout, are the Minneatta and Modoc. You will remark the absence of the names of the owners of the mines mentioned. I know but few of them, and to mention them would serve no purpose of this letter. I have simply mentioned mines which are destined to develop into paying ones. Many of them are now in the hands of poor men, and consequently development must be slow. I have met some owners of mines here who, while in conversation with them, would remark, "I hope nothing will be said about my mine until I get it open, so I can show something." That is the right view to take of the matter. Hoping this general view of the undeveloped and unknown mines may satisfy you until I can select and make special mention, believe me to be yours, truly.

A Miners' Clothes Room.

The Virginia Chronicle says: When the Consolidated Virginia works were reconstructed every department received equal attention, and the works are now as convenient and complete, for all purposes, as experience and money could make them. The miners' clothes room—an apartment sixty feet in length over the ore gangway—is for the special benefit of the men when they come out of the mine. They are then of course wet to the skin and much overheated. Making their way at once to the drying room, they take off their wet clothes and don dry ones. The room is thoroughly heated by an immense stove eight or ten feet long, surmounted by a huge sheet iron drum. The miners hang up their dripping working suits around the walls and across the room in all directions, and leave them there to steam and dry. When they have dried the windows of the room are thrown open, the accumulated vapor is allowed to escape, and then it is heated up for the next shift of wet workers. The room presents a remarkable appearance at all times.

A dealer in old clothes would view it with appreciative delight. The honest miner is not particular about the cut or condition of the garments which he wears in the lower levels. As long as they will hang on his shoulders and around his hips he is satisfied; and as to the hats which are worn in the presence of the bonanza, they are something fearful and wonderful to behold. They might be hung in a row in the most exposed hallway in the city and all the sneak thieves in Virginia might pass them in procession. The hats would be safe. The brogan of the miner is also more for use than for ornament, and could, if required, be used as a club with fearful effect. It is proposed to have at the Centennial Exposition at Philadelphia a collection of the different styles of garments worn in America from 1776 to the present day. If this idea shall be carried out, by all means let a hundred units be selected from the drying room of the Consolidated Virginia and sent on.

The Imperial Consolidated.

As there is now a good deal of talk about the proposed consolidation of the small Gold Hill mines, under the title of the "Imperial Consolidated," and as many are desirous of knowing about how the new shares should sell, a short review of the situation may not be out of place here. The consolidation, as we understand it, is to include the Imperial, 183½ feet; Empire mill and mining company, 75 feet; Bacon, 65 feet; Eclipse, 70 feet; Trench, 20 feet; Bowers, 20 feet; Gold Hill Quartz, 34½ feet—making a total of 468 feet. We understand the new arrangement will be represented by 500,000 shares, of which 200,000 are given the Imperial and Empire mill for their shaft, in the proportion of two-thirds to the Imperial and one-third to the Empire. The other 300,000 shares are then divided pro rata between the whole seven claims which are consolidated. This gives to the several claims the following shares: To the Imperial, 251,069; Empire, 114,744; Bacon, 41,666; Eclipse, 44,872; Trench, 12,820; Bowers, 12,820; Gold Hill Quartz, 22,009; total, 500,000 shares—an increase on the old stocks of these claims in the following proportions: Imperial (100,000 old shares), 2 51-100 for one; Empire mill (50,000 old shares), 2 29-100 for one; Bacon (25,000 old shares), 1 67-100 for one; Eclipse (25,000 old shares), 1 79-100 for one; Trench (5,000 old shares), 2 56-100 for one; Bowers, (5,000 old shares), 1 1-10 for one. In the foregoing we have not added the decimals to make it entirely exact, but it is within a fraction of right. The 468 feet are divided into 1,068 44-117 shares per foot. The old shares sold recently as follows:

Imperial, 100,000 shares at \$10.....	\$1,000,000
Empire, 50,000 shares at \$6.....	300,000
Bacon, 25,000 shares at \$5.....	125,000
Eclipse, 25,000 shares at \$5.50.....	137,500
Trench, 5,000 shares at \$5.....	25,000
Bowers, 5,000 shares at \$5.....	25,000
Gold Hill Quartz, 20,000 shares at \$3.....	60,000
230,000 shares for.....	\$1,702,500

Which is an average of \$7.27 per share. Seven dollars and twenty-seven cents per share for the 230,000 shares is equivalent to \$3.34½ per share for the 500,000 new shares, and is about the figure at which the new shares should start upon the market.

THE GOLD HILL MINE.—A correspondent of the Idaho Statesman says: The mill has run constantly since it started up, though for a few days last week it appeared doubtful whether ore enough could be obtained, in the present undeveloped condition of the mine, to keep it running. The closest game, however, has been played, and henceforth the facilities for extracting ore will increase daily. The company have a force of 48 men employed at present, including engineers and their very efficient foreman, W. H. McIlvin. Stopping operations, which were for a time suspended in the new levels, have again been resumed and under very favorable auspices. The ledge at the point where work is now being prosecuted is badly broken up, the formation reaching a width of 20 feet and upwards in places, while the vein carrying the entire wealth of the mine varies from a few inches to three or four feet. It is possible, and even probable, that at a greater depth all this ledge matter may unite in a well defined and gold bearing vein. If this proves to be the case, and the theory that it will is well grounded, I believe then Idaho can justly boast of one permanent and valuable institution, and Gold Hill will take rank with the famous mines of the coast. The financial countenance on this side the basin is wearing a more promising look than at any time during the past eight months.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy. Containing 672 Pages and 83 Engravings BY J. S. PHILLIPS, M. E., California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years. PRICE, bound in cloth, \$10.50; in leather, \$12. NOTICE.

Whereas, numerous persons have represented themselves as Agents of the FRYER PROCESS, the public are hereby notified that there are no authorized Agents. All business connected with the process must be transacted, until further notice, through the office of the FRYER NOBLE METAL MINING COMPANY, at Grass Valley, Nevada County, Cal.

ROBERT M. FRYER, Supt.

OF INTEREST TO MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially machinery for mechanical ore concentration, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

MINING ENGINEER.

A Mining Engineer, with the best of heat of reference, thoroughly experienced in the opening and superintending of mines and mills, desires an engagement Address "MINING ENGINEER," MINING AND SCIENTIFIC PRESS Office, San Francisco.

righted. Things are now working smooth, the usual shipments of ore taking place and the ore on the 8th, 9th and 10th levels pulps about the same as our former reports.

Arizona.

SELLING MINING GROUND BY LOTTERY.—Arizona Miner, Feb. 22: It is a conceded fact by all who have examined the ground that the Peck series is the richest mineral belt known to silver miners. The Peck series has been worked to any extent has afforded evidence, and is still maintaining this reputation, and doubtless many who read this and who know the character of the ledges will be astonished at the announcement that a portion of it is offered by lottery or otherwise, and yet it is true D. S. Lount, Esq., who, with Geo. Opydyke, owns the first South extension, both of the Peck and Occident of this series, has determined to close out his interests in Arizona with a view to going back to California to reside. He therefore offers his one undivided one-half interest both in the Chandler claim on the Peck ledge adjoining the Peck claim on the south, and in the General Kautz claim, which adjoins the Occident on the south, and is an extension of the ledge of that name, which is one of the Peck company's locations. The Peck taken from the Chandler and General Kautz claim, we are assured is precisely similar both in appearance and richness by assay to that taken from the discovery claims, of which they are adjoining extensions. Each of these claims contains 15,000 feet, in which Mr. Lount owns an undivided one-half interest—750 in each, or 15,000 feet in all, which he offers to dispose of in \$10 chances. There will be 150 tickets sold, and the highest number drawn will entitle the holder of that ticket to Mr. Lount's interest in both these valuable mining properties. Parties desiring to learn of the title are referred to the county records. They were both located on the 25th of June, 1875, and recorded on the 12th of July, 1875. The assessment work is all done until a year from the 25th of next June, and no adverse claimants to the property.

Colorado.

COOPER ON BEAR CREEK.—Denver Tribune, Feb. 23: The Malachite copper mine, located near Bear creek, four miles above Morrison, is being successfully developed by the Malachite mining company, and under the supervision of W. H. Chapman. This company is principally composed of Boston capitalists, has plenty of means at command, and sufficient knowledge of the business to avoid serious losses, which in Colorado mining proceed mainly from ignorance. The ore of this deposit, between walls, is some 23 feet, and the pay vein, so far as exposed, averages two feet in width, and is largely made up of red oxide of copper, with a fair quantity of the native material. At the works in Boston, where the ore will be treated, it will sell for some \$300 per ton, no allowance being made for the small quantities of gold and silver which this ore is known to contain. The owners are constantly engaged in the development of the mine, and they are raising an average of two tons per day. When this ore can be treated to advantage in Colorado, the profits of the mine will be largely increased.

THE RABBIT EAR SILVER MINES.—Boulder News, Feb. 19: Aware that many readers are depending on our paper for information respecting the silver mines of the mountain range which separates the Malachite and North Parks, we have endeavored to give all reliable information from that section. This is called the Rabbit Ear range, because from a distance its two prominent peaks have the appearance of the ears of a rabbit—a high rabbit, say the father of all rabbits, as the Irishman said of the jack. Where this range, coming from the west, strikes the main range, it "puts a tail on it," and the range is long as the Malachite mines are westerly from Long's Peak perhaps 30 miles, and northerly from Grand lake 15 miles. Of the older mining camps, Caribou is the nearest and the best outfitting point. Last summer three camps were founded there, the Campbell, Baker, and Pollard, the last being on the slope toward the North Park, and the two first named near the summit of the divide, and above timber line. The ore is much the same as the Georgetown silver ore, and, though 70 miles distant, will be shipped there for treatment; and it will bear the transportation till such time as mills are erected in the vicinity. The veins are of the large, strong class that produce a great deal of ore. Of its value so many tests have been made, both of samples and in bulk, that there can be no more question about it. By our visit to that region last August, we were convinced that it will prove one of the very richest of our silver regions. Within three years it is pretty safe to say there will be a stage line and telegraph from Caribou to Grand lake, connecting with a line to Georgetown, and also a line to Larimer City; and extensive silver mills will be erected in the immediate neighborhood of the mine. It is not impossible that a more direct road from this section to Grand lake may be had by crossing the range at the head of one of the forks of the St. Vrain. The exploration of that region is but just begun. Of those who went in there last season, most acquired property which they regard as a fortune, and about much of it there is no mistake. There are thousands of veins yet unclaimed there, and many fortunes will be secured next season.

Idaho.

NO WORK.—Idaho Avalanche, Feb. 24: Miners abroad who may be contemplating coming here in search of employment are recommended not to take this step at present. The labor supply here now is so large that the demand, and there still quite a number of workmen here unemployed. When spring opens there will probably be a change for the better.

SOUTH MOUNTAIN.—James Norton, assisted by Hugh Norton and R. M. Martin, has commenced work on the Robert Emmett. I went into the tunnel this morning. It starts on the lode and runs 30 feet before crossing it, for which distance there is a good haul on the lode on both sides of the tunnel, overhead and underneath. The pick cannot be struck in the walls or top or bottom without pulling out galena ore. They are now commencing to sink down on the lode and will be taking out good ore from the start.

H. KURRY and William Pierce will commence tomorrow to sink on the Dave Johnson mine, belonging to Messrs. Boyer & Butcher. The shaft is 30 feet deep to start with and the ore looks well.

T. J. VERTON continues to run his tunnel for the Polar Star lode and will tap it in the course of another month.

The Hastings Bros., with Patrick Heaton and Belmont Oontemache assisting them, continue operations on the Hastings mine. They have tapped the ledge in the west tunnel, which is six feet below the top of the ledge and the ore as good as they did above. These are the only mines that are being worked just now, but the Robie was taking out ore all winter until the last few days, and will resume a few days hence.

There is considerable hope that business will be revived ere long. If the South Mountain Consolidated Mining company's furnace can be leased, it is a settled thing that business will go on, and it seems only a pity to let them stand idle when by using them all here would have a chance to earn their living.

A BONANZA IN ALTURA COUNTY.—Idaho Statesman, Feb. 24: Geo. Newton, Judge Heath and Mr. Hogan, the owners of the Last Chance ledge at Atlanta, made one of the richest strikes on record in their mine last week. From five to six pounds of rock the size of the unparalleled sum of \$400, gold. If such a mine as this was situated in California or Nevada millions of money would be offered by capitalists to develop it; and the day cannot be far distant when the mountains of Altura county, which are ribbed and seamed with gold and silver, will command the attention of the world. From five to six pounds of rock the size of the unparalleled sum of \$400, gold. If such a mine as this was situated in California or Nevada millions of money would be offered by capitalists to develop it; and the day cannot be far distant when the mountains of Altura county, which are ribbed and seamed with gold and silver, will command the attention of the world. From five to six pounds of rock the size of the unparalleled sum of \$400, gold. If such a mine as this was situated in California or Nevada millions of money would be offered by capitalists to develop it; and the day cannot be far distant when the mountains of Altura county, which are ribbed and seamed with gold and silver, will command the attention of the world.

Montana.

MINING PROSPECTS.—Helena Independent, Feb. 20: The prospect for good mining season the present year is as bright if not brighter than for a number of years past. There is some apprehension that the water supply will be short in many localities, as the usual quantity of snow has not yet fallen, and weather prophets predict that it will not. If these predictions are verified, and no rain falls in the summer, the yield from the placer mines will be somewhat reduced from that of last season, but the yield from quartz—both gold and silver bullion—will be far in excess of that of any previous year in Montana's history. There is much greater activity now in the erection of machinery and the development of lodes than ever before known, and these developments indicate the existence of large quantities of very rich ore.

BUTTE.—Mr. Ben. Ezekiel, who returned from Butte last Monday evening, brings in some items from that promising camp. The Centennial mill started last Thursday for the purpose of testing the working of the machinery, which was found to perform admirably. The miners of that district promised Mr. How a bonus of 200 tons of first-class ore as an inducement to locate his mill at Butte, and it is said that the yield from this ore will pay for the mill. The first installment from the lode of Prof. W. Egbert Smith has already been delivered to the mill, and is now being reduced. The arrangement concluded between Mr. W. A. Olark and Mr. Farlin is giving satisfaction to all interested, and it is conceded that it will result favorably to the interest of mine owners in that locality. The Farlin mill will be in good working trim in April. The Poznański Brothers are owners of a valuable mine with a two-foot vein of ore containing gold, silver and copper. They are taking out considerable ore, which will readily sell at \$60 per ton on the dump. Morris Brothers have a fruit and variety store there and are doing a good trade. The population of the camp has greatly increased, and the Black Hills excitement is at a discount there. Mine owners are greatly elated at the prospects of the early development of their mines, and judging from present indications, their anticipations are extremely well grounded.

PATENTS & INVENTIONS.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

IMPROVED ZITHER.—Frederick Langmaak, S. F. This is an improvement in that class of instruments known as zithers. The instrument, which the inventor calls a "vocal zither," instead of having a large sound board with strings stretched across it and so constructed that it must lie on a flat surface, is made with a smaller sound board, and is provided with two posts or standards to support the head or wrist-bar which receives the turning pins. One of these posts forms the handle, and is provided with frets. The strings upon which the piece is to be played extend over this post, while the accompaniment strings are sufficiently separated to allow the fingers to grasp the neck and manipulate the strings above it without interfering with the others.

ATTACHMENT FOR BREACH LOADING RIFLES. Chas. D. Ladd, S. F. The object of this invention is to provide an attachment for breach loading rifles, by the use of which the breach loader can at any time be converted into a muzzle loader, with a convenient mechanism for removing exploded caps. Among the objections to breach loading rifles are the expense of the cartridges, and the uselessness of the piece if the hunter should exhaust his peculiar ammunition when at a distance from supplies of it. Another great trouble is that the fixed ammunition for breach loaders is usually made with heavy charges of powder and heavy balls, fitted for the largest game, but which would utterly destroy small animals or birds, besides making a very disagreeable recoil. In order to overcome these objections the inventor constructs a tube, having its exterior shaped precisely like a cartridge, so as to fit perfectly in the chamber of the rifle. In the front of this cylinder a small chamber is made, similar to the chamber of muzzle loading rifles, and this chamber has a passage extending back to the

nipple, which occupies the same position the anvil does in the ordinary central fire cartridge. As a percussion cap is used in this tube as in muzzle loaders, it is necessary to remove this cap after exploding. In order to do this, Mr. Ladd surrounds the tube with a loose ring, and a spring latch arm extends outward until its head is in such a position as to be caught by the retractor and drawn back with it. This action removes the cap from the tube, when the ring is stopped by striking a pin in the side of the tube. The continued movement of the hammer causes the retractor to slip past the latch, which, with the ring, will slip back so that a new cap can be placed upon the nipple. When the hammer is let down to its place the retractor will slide past the latch, and again be in readiness to withdraw a cap after the rifle has been fired. The charge of loose powder may be as large or small as desired, and can be inserted from the muzzle. The ball may be patched and seated by means of a ramrod in the usual manner, so that for such small game as hinds, squirrels, etc., a light charge of powder and a small round ball can be used, while the fixed and more costly ammunition can be reserved for larger game. The attachment can be readily seated by pressure at any time, and may be removed by forcing it out with a ramrod.

WINDMILLS.—Owen T. Davis, Brighton, Sacramento county. This invention relates to improvements in that class of windmills in which two wheels are mounted upon opposite ends of the same axis, and the improvements consists in a novel means for regulating the mill and throwing it into or out of the wind. In order to do this it is necessary to employ a tail, which stands at right angles with the wheel shaft, being mounted in an arm so that it can rotate upon its axis. A crank is made at the end of this axis and a suitable connecting rod leads to the lever below the arm. This lever is pivoted near its center and a weight is suspended from the end of it so that it will force up the opposite end of the lever and through the connecting rod act upon the crank and thus retain the tail in a horizontal position. From the middle of the lever an arm extends upwards, and has the double winged tail attached to it. This tail has two leaves shaped like the shaves of a plow, flaring out at the top and having their front edges joined. The operation will then be as follows: During any ordinary breeze the wheel will stand to the wind, and the tail will lie horizontal. Whenever the wind increases to a gale it will act upon the side of one of the flaring wings in the manner of a propeller and thus force it back. This forces the lever down and through the connecting rod operates the crank and thus turns the tail so as to present its flat side to the wind, which will then force it around until the wheels are carried out of the wind. When the wind abates the weight will act to partially or wholly overcome the action of the wind upon the inclined wings and thus turn the tail so as to again allow the wheels to be brought into the wind.

FEATHER DUSTER PROTECTOR.—Jacob Unna, S. F. This invention relates to a device to be applied to feather dusters for the purpose of preventing the outside feathers of the duster from spreading and being broken when the duster is introduced between articles of furniture, or in small spaces. When the outside feathers of feather dusters are allowed to straggle out in every direction, the appearance of the duster is spoiled. It soon becomes ragged and broken, and its work as a duster is not accomplished. Mr. Unna uses a band of leather or other suitable material, which is large enough to pass loosely around the feather duster near its middle and confine the outside feathers to their place without crowding them together. An India rubber band is made small enough to clasp the head of the duster tightly when drawn over it. Then two bands are connected by means of stays or braces, two usually being used. The elastic band clasps the head of the duster, while the other band passes around the middle of the feathers, the springy metallic bands connecting the two. The device prevents the outside feathers from spreading and being broken or lost out of their proper places. The bands can be slipped back and forth, so as to clasp the broom near its extremity or close to its head. This device is not a clamp, but a loosely fitting band, and is in no way similar to the broom and brush clamp now in use.

Notice to Proprietors of British Patents.

We append a list of British patents, secured through the MINING AND SCIENTIFIC PRESS Patent Agency, upon which the British tax becomes due in the year 1876. Proprietors of these patents should see that their patents and the amount of money required to pay the tax and agency fees is deposited with us at least one month prior to the day upon which the tax is due:

No. 1,291 (1869), Hawkhurst & Pollock, preventing corrosion of steam boilers, £100, due April 25th; No. 1,568 (1869), Johnston, distilling apparatus, £100, due May 19th; No. 1,062 (1873), Van Laak & Gillespie, bungs and bung inserters, £50, due March 20th; No. 1,298 (1873), Shaw, printing type and tools, £50, due April 7th; No. 1,753 (1873), Huntington, steam boilers and furnaces, £50, due May 14th; No. 2,005 (1873), McWilliams, sheep shears, £50, due June 4th; No. 2,037 (1873), Stehns & Co., hoisting apparatus, £50, due June 9th; No. 2,067 (1873), Niel, reifier for distilling apparatus, £50, due June 10th; No. 2,435 (1873), Fisher, preventing oxidation of metals, £50, due July 14th; No. 3,613 (1873), Seward & Phillips, musical staff, £50, due Nov. 6th.

Inspecting Steam Boilers.

Pullen's bill for "The appointment of Inspector of Steam Boilers and Steam Tanks and for the better security of life and property in the city and county of San Francisco" reads as follows:

SECTION 1. There shall be appointed by the Board of Supervisors of the city and county of San Francisco, on the first Monday in May, or as soon thereafter as practicable, one Inspector of Steam Boilers and Steam Tanks, who shall hold office for the term of two years. The term Inspector hereafter in this act used shall mean Inspector of Steam Boilers and Tanks for the city and county of San Francisco.

Sec. 2. The Inspector shall have at the time of his appointment a chief engineer's certificate from United States Inspectors.

Sec. 3. The Inspector shall, upon application in writing of any owner or owners, inspect all stationary boilers and steam tanks used within the city and county of San Francisco for generating steam to drive or work machinery, and at least once in every year thereafter he shall subject all boilers to the hydrostatic pressure, and shall satisfy himself by thorough examination that such boilers or tanks are well made and of good and suitable material, that the arrangement for delivering the feed water is such that the boilers cannot be injured thereby, and that such boilers and machinery and the appurtenances may be safely employed in the service proposed in the written application, without peril to life or property. In subjecting to the hydrostatic tests boilers usually designated and known as high pressure boilers, the Inspector shall assume 120 pounds to the square inch as the maximum pressure allowable as the working power for a new boiler of 42 inches in diameter, made in the best manner, of inspected American iron plates, one-fourth of an inch thick, and of a quality required by the law governing United States Inspectors of Steam Boilers, and shall rate the working power of all high pressure boilers, whether old or new, according to their strength, compared with this standard, and in all cases the test applied shall not exceed the working power allowed in the ratio of 180 pounds test pressure, to 120 pounds to the square inch, working pressure. Should the Inspector be of the opinion that any boiler, by means of its material or construction, will not safely allow so high a working pressure as is above described, he may, for reasons to be stated specially in his certificate, fix the working pressure of such boiler as he in his discretion may deem proper, provided that the pressure so fixed shall not exceed two-thirds of the test pressure.

Sec. 4. Every boiler shall be provided with a good, well constructed safety valve, or valves, and shall be provided with a sufficient number of gauge cocks. The Inspector shall license and classify engineers of stationary engines. It shall be unlawful to employ any person, or for any person to serve as engineer of any stationary engine, who is not licensed by the Inspector, and any one who violates this section shall be guilty of a misdemeanor, and each day of such employment or service shall constitute a new offense.

Sec. 5. Every engineer who receives a license, shall, before entering upon his duties, make oath before the Inspector, to be recorded with his certificate, that he will faithfully and honestly, according to his best skill and ability, perform all the duties required of him by law.

Sec. 6. If any engineer shall refuse at any time to admit into his engine room any person whom the owner may desire to place there for the purpose of learning the profession of engineer, his license shall be revoked upon proof satisfactory to the Inspector of such refusal.

Sec. 7. The Inspector shall receive the sum of \$3 for every stationary boiler or tank so inspected by him, the same to be paid by the person or persons, firm or company, having the boiler in use, and for each engineer licensed the Inspector shall receive from the person so licensed the sum of \$2.

Sec. 8. Within fifteen days after his appointment and qualification, the first Inspector appointed under the provisions of this act shall publish or cause to be published once a week for at least four weeks, in at least three daily newspapers printed and published in the city and county of San Francisco, a notice of his appointment, and requiring all persons owning or using any stationary steam boiler or tank situate within said city and county, to report to him in writing the location of any and all such boilers or tanks owned or in use by him or them, and the business or purpose for which such boilers or tanks are used; and all such owners or users shall, within thirty days after the publication of said notice, make the report provided for in this section. And any person intending to erect or use any steam boiler or tank shall in like manner, and without notice, report to the Inspector the location and purpose of such steam boiler or tank, so that the same may be inspected before being used. Any person violating any of the provisions of this section shall be guilty of a misdemeanor.

Sec. 9. The Inspector shall give bonds in the sum of \$10,000, with security to be approved by the Judge of the County Court of the city and county of San Francisco, and the said Inspector shall by the judge of the said court be duly sworn or affirmed to perform the duties of his office, and that he will not accept any money, gift, gratuity or consideration whatever

from any person or persons whomsoever, during his term of office, except such as shall be prescribed in this act; and upon conviction of violation of such oath or affirmation before any court of competent jurisdiction he shall be subject to a fine not exceeding \$2,000, and to undergo an imprisonment in the county jail of the said city and county, not exceeding one year, both or either at the discretion of the court.

Sec. 10. The Inspector shall provide all requisite apparatus, machinery and stationery for carrying this act into effect, to be approved by the Board of Supervisors, and paid for by the Inspector out of the moneys received by him for inspection and licenses.

Sec. 11. The penalties and forfeitures which may be incurred for offenses against this act may be sued for, prosecuted and recovered by action to be brought in any court of competent jurisdiction by the Inspector in the name of the people of the State of California, and the moneys collected in such action, less the costs and expenses incurred in the prosecution of such action, shall be paid over to the Treasurer of the city and county of San Francisco.

Sec. 12. This act shall take effect on and after the first Monday in May, 1876.

SENATOR JONES says that, without exception, all the newspaper articles purporting to describe what his hill or speech on the silver coinage question will contain are unauthorized, incorrect and imperfect. He withholds a description of the plan until an explanatory report is ready to accompany it.

New Books.

"SAFETY VALVES" is the title of No. 21 of Van Nostrand's Science Series, for sale in this city by Payot, Upham & Co. Richard H. Buel, C. E., the author, does not pretend to offer much that is original, but has strived to gather what is valuable from the great mass of material to be found in scientific periodicals and in publications that are not generally accessible. An endeavor has been made to systematize the treatment of the subject and to give such varied solutions of the problems that arise in proportioning the parts of safety valves as to render them plain to those who have only an elementary education. The importance of having the general principles of safety valves understood by those who are charged with the care of steam machinery cannot well be overestimated. With a safety valve that is in reality all which its name implies, a large proportion of the risks incident to the use of boilers will be avoided; while on the other hand, a safety valve that is only such in name, is one of the readiest assistants to a disastrous explosion. This quotation from the author's introductory shows what the work is. We opine that it will be instructive and useful to engineers and others having anything to do with steam boilers.

COLOMBIAN BUSINESS DIRECTORY AND ANNUAL REGISTER FOR 1876.—This work contains a classified list of all the business and professional men, officers, societies, schools, churches, etc., in all cities and towns of Colorado, together with postoffices, express and telegraph, railroad and stage offices. This is the second annual volume of the directory and it contains much useful information concerning the resources of the Territory, as well as the lists mentioned. We are indebted to J. Alden Smith, Territorial Geologist, for courtesy in sending this publication. We extract the following concerning the coal mines of the Territory: "The principal coal mines are in Boulder, Jefferson and Weld counties, north, and Fremont, Las Animas and Conejos, south of the divide; the most extensive measures are in Boulder county. The coal of Colorado can be divided into three classes: First class—anthracite of Gunnison river and branches, non-coking, contain 150 per cent. water, 91 per cent. carbon. Second class—coking coal, Trinidad, 8.84 per cent. water, 59 to 64 per cent. carbon. White river coal contains 85 per cent. carbon, 4 per cent. water. Third class—non-coking, Murphy, Marshall, Golden, and Baker coal contains on an average 13 per cent. water, 31 per cent. volatile matter and 52.20 per cent. carbon. Eighteen coal mines, extending from Canon City to the St. Vrain river, produced from January 1st, 1864, to October 1st, 1875, 511,154 tons, valued at \$2,044,610. The value of the entire product in 1870 was estimated at \$375,000; in 1873, according to the Governor's message, \$1,000,000. The yield for 1875 must have reached \$1,500,000."

UNITED STATES GEOLOGICAL SURVEY OF THE TERRITORIES.—We have received Bulletin No. 6 of the second series of these pamphlets, issued by the Government. This number contains: "An Account of the Various Publications Relating to the Travels of Lewis & Clarke with a Commentary on the Zoological Results of their Expedition," by Dr. Elliott Cress; "Notice of a Very Large Goniolite from Kansas," by F. B. Meek; "Fossil Orthoptera from the Rocky Mountain Tertiaries," by Samuel H. Scudder; "Studies of the American Falconidae," by Robert Ridgway.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

EDGEWOOD G. & S. M. Co.—February 24th. Location, San Bernardino county, California. Directors—Joseph A. Wells, Joshua J. Ayres, J. M. Hackett, C. A. Burr and C. D. Morrison. Capital stock, \$5,000,000.

BELLEVILLE M. Co.—February 25th. Location, Columbus district, Esmeralda county, Nevada. Directors—E. M. Fay, Walter Turnbull, Geo. W. Fisher, Wm. H. Sears and A. W. Rose, Jr. Capital stock, \$5,000,000.

ROUCH & READY G. & S. M. Co.—February 25th. Location, Nevada county, Cal. Directors—L. L. Brown, T. D. Bradford, N. B. Childs, T. L. Bibbins and J. M. McCrory. Capital stock, \$5,000,000.

VERITAS CONSOLIDATED G. & S. M. Co.—February 25th. Location, Storey county, Nevada. Directors—E. J. Baldwin, Robert Sherwood, Samuel T. Curtis, James M. Galloway and J. P. Cavalier. Capital stock, \$11,500,000.

SOUTH END M. Co.—February 25th. Location, State of Nevada. Directors—Edward F. Stone, W. S. Lyle, John S. Rae, R. N. Graves and J. M. Walker. Capital stock, \$10,000,000.

CITY OF BOSTON M. Co.—February 24th. Location, Virginia mining district, Nevada. Directors—F. A. Morgan, Frank Otis, B. L. Brandt, A. G. Burnett and E. W. Smith. Capital stock, \$10,000,000, in 100,000 shares of \$100 each.

FONTANA M. Co.—February 25th. Location, Esmeralda county, Nevada. Directors—Harry W. Pummer, O. P. Ferry, Cornelius Platt, Giuseppe Fontana, Arazio Stiglieno, Charles E. DeLong, Braggio Guererro, William Mann R. Johnson and Thomas Pettinelli. Capital stock, \$10,000,000, in 100,000 shares of \$100 each.

CENTRAL M. Co.—February 20th. Location, State of Nevada. Directors—Philip Kitz, J. B. Harfield, J. Pershacker, John G. Kno, K. Louis Kaplan. Capital stock, \$10,000,000, in 100,000 shares of \$100 each.

JOSEPH ROSSI, an Italian miner, 34 years old, was buried by a cave near Volcano, Saturday, and instantly killed; three other men who were with him barely escaped.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

California Acclimatizing Society—Location of principal place of business, San Francisco, Cal. Notice is hereby given, that at a meeting of the Board of Directors, held on the ninth day of February, 1876, an assessment of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin to the Secretary, at the office of the company, room No. 37, Nevada block, northwest corner of Pine and Montgomery streets, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the fourth day of March, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the third day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expense of sale. W. W. FAY, Secretary, pro tem. Office, room 37, Nevada block, San Francisco, Cal.

Josephine Gravel Mining Company—Principal place of business, San Francisco, Cal. Location of works, Brushy Canon, Placer county, Cal. Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-third day of February, 1876, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold and silver coin, to the Secretary, at the office of the company, 531 California street, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the tenth day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expense of sale. W. M. SMALL, Secretary. Office, No. 531 California street, San Francisco, Cal.

Mariposa Land and Mining Company of California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa county, Cal. Notice is hereby given that at a meeting of the Board of Directors held on the twenty-third day of February, 1876, an assessment of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States currency to the Secretary, at the office of the company, room 33, Nevada block, No. 309 Montgomery street, San Francisco, Cal. or to the Agent-Secretary, at the office, No. 9 Nassau street, New York, N. Y. Any stock upon which this assessment shall remain unpaid on the twenty-fourth day of March, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before will be sold on Monday, the tenth day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expense of sale. By order of the Board of Directors.
LEANDER LEAVITT, Secretary.
Office, room 33, Nevada block, No. 309 Montgomery street, San Francisco, Cal.

New England Tunnel and Smelting Company—Location of principal place of business, San Francisco, Cal. Location of works, Tulare county, Cal. Notice is hereby given, that at a meeting of the Board of Directors, held on the fifteenth day of February, 1876, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin to the Secretary, at the office of the company. Any stock upon which this assessment shall remain unpaid on Saturday, the twenty-fifth day of March, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the fourth day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expense of sale. CLINTON C. TRIPP, Secretary. Office, room 10, No. 401 California street, San Francisco, Cal.

The Northwest Silver Mill.

The following interesting description of the new silver mill of the Northwest company, at Philipsburg, Montana, which has recently made so promising a start, is furnished to the *New Northwest* by a special correspondent at Philipsburg:

The Building.

131 feet long, is upon a side hill, and is on the terrace plan, containing four steps or stories. The ore road along the hill side, 12 feet above the upper story, makes a fifth step or terrace.

The fourth or upper story, 22x40, is the ore room, containing a Blake rock breaker, through which the ore is fed and falls upon the drying floor in the story below.

The next (third) story, 36x40, contains first the drying floor, which is simply a horizontal floor, 4x4, from the furnaces, built across the mill and back to the stack, covered with iron plates, thus giving a drying surface, 8x40 for ore, and 4x30 for salt. When dry, the ore is shoveled into a car, and, after weighing, dumped before the batteries. Of these there are two or five 700 pound stamps each. The stamps each drop seven and a half inches one hundred times per minute. The ore dusts through brass wire screens of 3,600 meshes per square inch, whence it is automatically conveyed into sheet iron hoppers, three in number, one above each furnace.

The next story, 40x65, contains two rooms—the roasting room, 38x40, and the cooling room, 38x25. In the roasting room are three Bruckner furnaces, the first ever used in Montana. These are cylinders of boiler iron, five and a half feet in diameter, 12 feet long, set horizontally, lined with ordinary brick and having inside a screw shaped partition or diaphragm, which at each turn shifts and mixes the ore. Each end of the cylinder has a neck in front connecting with a fire box, and in the rear with a condensing flue. The cylinder rests upon friction rollers, and is revolved by means of cog gearing about 25 times per hour. The ore is let fall from the hoppers above into the cylinders through doors, and is discharged when roasted, by the same doors into a car. The car is drawn into the cooling room, which is paved with brick, and there dumped.

The lower story, 35x77, has three rooms. First the hoiler and engine room, 25x35; next the amalgamating room, 38x35, and then the retort and smelting room, 18x35. The amalgamating room is in three floors. The upper floor, on the same level as the cooling room, has a car in which the roasted ore is taken to the pans. There are three pans now running, and two more will soon be put in. A fall of about four feet from the pans brings ore to the level of the settlers, of which there are now two, and a third to be added. Then a descent of about seven feet to the lower story, on which level are the engine and smelting rooms. The engine is twelve inch bore and 20 inch stroke, and does its work easily and well.

The Method.

After drying and crushing, the ore in charges of 3,000 pounds is let into a cylinder with five per cent. of salt. A quick beat is applied until the ore is thoroughly warmed, when the cylinder is put in motion and kept revolving at a varying heat, according to the condition of the ore, until the charge is done. That point is known by the smell of the roasting ore, and also by chemical tests. The roasting of this ore takes from five to seven hours per charge of 3,000 pounds. It is then dumped and cooled, either with time or water. It is then taken, in charges of 1,000 pounds to the small pans, and 2,000 pounds to the large pan, mixed with water to a very thick paste and steam applied. In from two to two and a half hours from 20 to 25 per cent. of quicksilver is put in the pans, which then are let run four to six hours longer. Then water is added until the pulp is thin, when the pan is discharged, the pulp and part of the quick flowing into the settler. The rest of the mercury is caught in vessels and strained through canvas socks. The residue is an amalgam of about one part of silver to five parts of quick. This is retorted and smelted into bars. The pulp from the settlers, now reduced to refuse "tailings," is gradually drawn off in time to leave the settler free for the next charge.

The Results

Thus far are very satisfactory. But one charge has been roasted to less than 90 per cent., the average reaching nearly 92 per cent. of the assay transformed into chloride of silver, fit for amalgamation, and samples of the "tailings" taken every hour in the 24, show that less than 10 per cent. of the assay is running off. In 24 hours the engine burns five, the cylinders four, and the dry-kiln one and a half cords of wood. The men employed for 24 hours are: Blake crusher, one; dry-kiln, three; stamps, three; cylinders, two; cooling floor, two; pans, two; one amalgam drawer and retorter; two engineers and one woodman; in all 17 men, besides assayer and foreman. The engine and boiler, the stamps in part, the shafting, flanging and dry-kiln plates were furnished by Davis & Tatem, of Helena; the sheet iron work and hardware by Kinna & Jack; the pans and settlers from San Francisco and from Chalmers & Co.; the cylinders by Lane & Bodley, Cincinnati, Ohio. The mill was built from plans furnished by Charles E. Sherman, agent for the Bruckner cylinders.

Two men were drowned in the Rock Island mine on the Comstock this week, while tapping a winze filled with water.

The Simplest, Cheapest, Most Effective and Durable

Power Drill is the New

"CALIFORNIA" ROCK DRILL,

MANUFACTURED BY

HAWKINS & CANTRELL, San Francisco, Cal.,

AND SPECIALLY DESIGNED TO MEET THE REQUIREMENTS OF MINERS ON THE PACIFIC COAST

The HARRISON Burr Stone MILLS. \$1000 CASH Offered for their EQUAL. Will grind any thing. Send stamp for new Illustrated Catalogue Just issued.

PRICES 60 percent less than any other mill in market. 240 bush. corn ground in 10 hours in \$150 mill. Weight 500 lbs. Manufactured by Edw. Harrison New Haven, Ct.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonder fully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

Are the only Agents for sale of these
Engines in the Pacific States.

Hoisting Engines. Mining Engines.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been too long in use on the Pacific coast to require any special recommendation from us. They are well known from Alaska to Mexico. We would refer with confidence to any one of the hundreds in use. They still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship to compete with cheaper engines. They have lately been greatly improved by adding large drums, and reverse motions.

MINING HOISTING ENGINES.

Farmers, Take Notice. The Most Important Invention of the Age.
THE ENAMELED STEEL BARBED FENCE WIRE,
Patented by J. F. GLIDDEN.

It makes the most durable, safe, and reliable fence in the world against stock of all kinds.

The GLIDDEN PATENT BARB WIRE has been tested by thousands of practical farmers, who universally recommend it. We ask you to try it for the following, among other reasons: 1. If it does not answer the recommendation, you can return it and your money will be refunded. 2. It is the cheapest and most durable fence made. 3. It takes less posts than any other fence. 4. It can be put up for one-quarter the labor of any other fence. 5. Cattle, mules, and horses will not rub against and break it down. 6. The wind has no effect upon it, and fires will not burn it up. 7. Stock will not jump over or crowd through it. 8. Your crops will be safe as far as fence is concerned. 9. You will know where your stock is by night as well as by day. 10. You can draw enough in a buggy to fence 100 acres, and two men can put it up in two days. 11. Because it is what every farmer needs. 12. Because it was invented by a practical farmer and you will say, after a fair trial, it is the BEST FENCE IN THE WORLD! 13. The change of seasons has no effect upon it—it being twisted, holds its tension. 14. The wire is manufactured entirely from steel, which has a relative strength of over 30 per cent. greater than that of any common iron wire. 15. The only steel covered wire. 16. The only barb that cannot be displaced with thumb or finger, or cattle's horns. 17. The only barb with prongs projecting from between the twisted wire, and cannot be bent, broken, or rubbed off, and never need replacing. 18. The only coiled barb with broad base on main wire, which renders it immovable. 19. The only barb wire which, during process of manufacture, its strength is tested equal to that of two-horse power. 20. The only barb put on by machinery—it is not pounded on with hammer and indented in main wire to hold its place. 21. The only barb wire that gives universal satisfaction, and has greater sale than all others put together. 22. Be sure and ask for the GLIDDEN PATENT BARB WIRE. Enquire of Hardware and Agricultural Dealers. Samples sent free of charge by addressing

The Abbott Concrete Pavement.

EDITORS PRESS.—An examination of the streets of San Francisco has satisfied me that they can be paved more economically and satisfactorily, with a bituminous concrete than with any other material. Having been engaged for many years in street paving of various kinds, but making a specialty of concrete in Eastern cities, some of my observations of the facilities for making such pavement in your city, may be of interest to your readers. My object in investigating the subject here has been to obtain information for a Massachusetts company, which has secured of me the rights for this State, and is now making arrangements to locate here permanently, with the capital and machinery necessary to do a street paving business.

There are several varieties of bituminous concrete used for pavements, all of which have been patented, and many have been successfully used. I shall write particularly of the kind known through the East as the "Abbott concrete," which I have been engaged in developing and perfecting for the last six years. The materials for such pavements as I shall describe are here in abundance; the climate is peculiarly favorable, the slight variation in temperature making it possible to overcome the difficulties experienced where changes of 100 deg. are constantly taking place. The sand foundation prevailing is favorable, making a good bed for the concrete, which, being absolutely waterproof, keeps the foundation dry, and no throwing of the pavement will occur, as in those varieties of pavements that are full of joints, which constantly allow the water free access to the foundation. These favorable conditions existing here, by which economy of construction and a reasonable durability are secured, the introduction of a pavement of this character becomes of great interest to all who desire clean, quiet roadways. The public is likely to think unfavorably of concrete from the fact that so much unevenness appears in the asphalt sidewalks, so common in this city, and yet the fact that so large a proportion of these walks are perfect, shows that good work can be done, if the proper conditions are secured.

The success of any concrete mixture depends very much on the uniformity of materials used, the exactness with which the proper proportions are arranged and the thoroughness of the workmanship. Unless strict attention is given to these points, the best material will be spoiled. This accounts for much of the failure so commonly experienced by novices in the business, and the realization of this fact has led me to personally supervise the introduction of my pavement into any new field. In

The Abbott Process, refined asphalt, either natural or artificial, is tempered to the proper consistency with creosote, which is the heavy oil extracted from coal tar by distillation. This composition is used at a heat of 400 degrees, to secure which a very strong, air-tight tank is used. A pyrometer indicates the temperature, and a fire box and flues are so arranged as to regulate the heat. These tanks can be made stationary or movable, according to the use required of them.

The system was invented by T. New of New York, and by it the possibility of manufacturing a uniform quality of material has been demonstrated. Before this invention, open kettles were used to melt the asphalt, the material was imperfectly melted, 250 degrees being about the highest heat obtained, and very unevenly distributed, while contact with the air caused evaporation largely to take place. By the tank system, large quantities of material can be held at the proper heat for any length of time without loss by evaporation. The gravel used in this process is also heated to 300 degrees by means of revolving heaters, constructed especially for the purpose. These heaters are worked by horse or steam power, and constant motion of the gravel is kept up, by which a circulation of hot air is provided, and an even heating of the gravel secured. This gravel heater is shown in Fig. 2. The hot gravel and composition are then rapidly mixed in definite proportions, by horse or steam power, and the mixed material carted to

the street, where it is spread and rolled with heavy rollers, setting firmly as it cools. To properly carry on street paving, machinery enough must be employed to turn out material with such rapidity that the joining of one load with another on the street shall be made while the material is hot. For the

Heavy Traveled Streets

of this city, I should recommend the following treatment:

Prepare the road bed so as to require a pave-

ment and thoroughly paved in the method described, will present the following

Advantages Over Other Kinds of Pavement.

Its cost in this city will not exceed that of the best stone pavement. It will not be thrown out of place by the swelling up of water underneath, as the solid crust of seven inches thickness is entirely waterproof, and will actually resist water from the upper or under side. It will be a quiet street, because wheels move noiselessly over its surface, and no sound will

Fig. I.

MOVABLE AIR-TIGHT TANK FOR MELTING REFINED ASPHALT.

ment seven inches thick. Roll the sand foundation well with a steam roller weighing not less than five tons. Lay a foundation of solid concrete four inches thick, composed of coarse gravel or broken stone, and the asphaltic composition described. Roll it with the steam roller while hot, and when it has cooled a firm,

be heard, except from the horses' hoofs. It will save much wear and tear on horses, vehicles and horse shoes, besides affording much comfort and pleasure to the riding public. It will be healthy, because its smooth surface is easily kept clean, and no crevices are found for the lodgement of filth. Heavier loads can

REVOLVING GRAVEL HEATER FOR ABBOTT PAVEMENT.

herd foundation is secured. Surface this foundation with a three-inch layer of finer concrete made in a similar manner, grading and rolling with great care. Over this surface spread a hot

be hauled on it then on stone pavements, for there is no rough, uneven resistance to wheels. The Materials Are Imperishable, And, under the right system, such pavements

Fig. III.

SECTION OF ABBOTT PAVEMENT.

liquid asphaltic composition prepared for the purpose, and finish with clean, fine, hot gravel, rolling it in while hot. This done, the pavement is finished and ready for use. It will then have the appearance of the section of pavement shown in Fig. 3. A street, honestly

can be kept in repair at very light expense. The foundation need never be disturbed, while I estimate that the surface can be kept perfect for 10 years at an expense of not more than 50 cents per square yard, and left at the end of the ten years as good as when new.

But it will be asked, where has this pavement been tested, and how long. In Brooklyn, N. Y., it has been in use six years, and is now laid on over 12 miles of streets. In Cleveland, Ohio, it has been used five years, and is laid on over six miles of streets, including the beautiful Euclid avenue. In Washington, D. C., it was laid, three and four years ago, on about eight miles of streets, and the same character of pavement is laid on about 30 miles of streets in that city. In these three cities it has received the only practical test, constant public use for a series of years, and it has been found to answer all the requirements in economy and durability, while at the same time affording the most luxurious roadway for driving purposes that can be made. During the last year I have introduced it into the cities of Boston, Philadelphia, Providence, Chicago, St. Louis and Columbus, Ohio. It will be introduced here during this year, and this city, which, in many respects, is the most attractive in the country, though sadly deficient in good street pavements, will have the opportunity to beautifully and permanently improve its highways by this method. If any of your citizens, who visit the Centennial, would like to see for themselves how this pavement appears in practical use, let them give me a call at No. 16 Court street, Brooklyn, N. Y., and they shall take a ride over 12 miles of it behind a good team. N. B. ABBOTT.

S. F., Feb. 25th, 1876.

[We are pleased to meet Mr. Abbott here on such a mission. He comes personally well recommended, and at our special request has written the above communication, which to all interested in the important subject of good pavements, will repay perusal and consideration. We hope no time will be lost in giving us the first test of the work in this city, where at present we are sadly afflicted with very bad pavements.—Eds. Press.]

THE GEOLOGICAL SURVEY.—Although the bill for the continuance of the State Geological Survey was introduced in the Legislature some weeks since, nothing definite has yet been done with it. We hope the Legislature will make the necessary appropriation for carrying on the necessary work, as the amount asked is small and will do great good. Mr. W. A. Goodyear, who is mentioned favorably for State Geologist, is perfectly familiar with the wants of the miners, and would do what he could to please them. He is familiar with all the details of the former survey, and is better calculated than any one else to finish the work already commenced. Mr. Goodyear is a mining engineer, and would no doubt bestir himself to give us a volume in economic geology, and hunt up facts of interest and importance to the mining community. There is no good reason for stopping any longer a work which cost so much, when so little is left unfinished.

MINING MACHINERY.—Messrs. Parke & Lacy, agents for the Burleigh drilling machinery, Putnam Machine Co.'s machinists' tools, Haskins' engines and boilers, Farmer's electric machine for blasting, Hill's exploders, etc., have recently removed to a fine new building at No. 417 Market street. In these new quarters they have a fine commodious salesroom, where they are able to display samples of the various articles for which they are agents. They keep a very full line of mining machinery, which these interested in mining machinery will do well to examine. Their card will be found in our advertising columns.

It will take five cars to transport the Central Pacific railroad company's collection for the Centennial exhibition to Philadelphia. A recent addition to the display consists of a jar of earth from each agricultural district of the State, with accompanying specimens of grain raised from the soil. A number of ethnological specimens, belonging to the Academy of Sciences, is to go with the railroad company's collection.

A WORKMAN in the San Fernando tunnel, named Sullivan, was killed by a giant powder blast on Wednesday afternoon of last week, the charge hanging fire, and, when he went to examine it, going off and blowing a pickaxe entirely through his body.

CORRESPONDENCE.

Botanical Excursions.

[Written for this Press by J. G. LEMMON.]

No. 1.—Pyramid Lake and Humboldt Desert.

"Mr. Gray advises me to solicit you to collect specimens of the trees and shrubs of your region of country for exhibition at the Centennial. Can you undertake the work and do it well, according to specifications following. Also, will you make a collection of the general flora for me?" writes Dr. Geo. Vasey, botanist of the Agricultural Department at Washington.

This request was received in my snow-covered retreat at Webber lake, April 8th, 1875. I replied at once, accepting the task, and the evening of the second day after found me 40 miles on the great basin, gathering the early evanescent flora of that strange region.

But one can do little collecting alone, so I led my curly pony, packed to his ears with plants, back to Sierra valley, and beset in his school-room my companion on so many excursions, Prof. E. L. Cese, to accompany me on in the great basin to Pyramid lake—one of the reservoirs or residual seas of this once vast ocean. Thinking of the heavy labor and fierce exposure it involved, the Professor at first hesitated, but by dint of glowing descriptions and strong promises, he kindly consented.

Stowing our little wagon with bedding, food, and great beles of botanical paper, we scrambled down the long east side of Sierra valley, 35 miles to Beckworth pass, through which we emerged into the great Fremont basin, to toil for weeks through its sand, alkali and prickly bushes, revel in its curios and rare flora, gaze upon its grand yet gloomy scenery, and bring away—beside the characteristic products of the basin—a train of vivid, treasured memories of strange scenes and striking adventures in that wonderful sun-scorched land—a veritable *tierra caliente*!

The Great Basin.

The great basin of America is the bed of the evaporated Mediterranean sea of the western continent. Situated on the same parallels as its Eastern prototype, bordered like that on all sides with high ranges of mountains, it differs from it in two particulars, which render the one a very salt sea and the other a very salty desert.

The Mediterranean sea fills a deep chasm in the earth's crust 2,000 to 6,000 feet deep; lying between 30 deg. and 46 deg. north lat., and almost constantly swept by the dry winds of the great Sahara, its waters are evaporated at an immense rate, which would, ages ago, have emptied its basin but for the other important fact, the Strait of Gibraltar, through which a strong current ever comes from the ocean; and this, in addition to the mighty rivers which empty into the sea, and all to restore the equilibrium disturbed by evaporation. To this evaporation—this lifting of a sea into the air—is Europe indebted, mainly, for its exceeding fertility. The dry South wind is a sponge which takes up the waters of the Mediterranean and, condensed by the cold summits of the mountains of Europe, showers its waters over the plains. To this fact also is due the intense saltiness of the Mediterranean, for salt is the residuum of evaporation.

The Mediterranean desert of America is elevated about 5,000 feet above the ocean, so its waters would naturally sink in the earth. Then there are no mighty rivers feeding it, much less a Gibraltar strait, bringing in a flood from a neighboring ocean.

The towering rim of mountains on the West prevents the moist winds of the Pacific from entering the basin; the lofty Eastern rim bars out the Gulf winds; the lower North and South rims admit only the hot, dry, South winds of the Colorado to sweep over the basin, absorbing at their founts the few meager springs that rise in the mountain borders; so we have an immense frying pan or bake oven, as if scooped out of the highest mountains of North America.

It is oblong-elliptical in shape. Its western end rests upon the snow-clad Sierra, the eastern upon the lofty Wasatch range—a spur of the Rocky mountains. On its smooth bottom are ranged, side by side, steep ranges of mountains running north and south, like cross-bars of a gridiron. The highest of these, the Humboldt range, divides the basin exactly in the center, and the short rivers running from the mountains on all sides form sinks or salt lakes in each end, to which numerous systems of hot springs add alkali, sulphur and other minerals, so that the sinks are generally extremely offensive.

The most important rivers of the eastern depression are Bear river, on the north, and Sevier on the south, each emptying respectively into Great Salt Lake and Lake Sevier. The rivers of the west end are Humboldt and Susan on the north, debouching respectively into Humboldt sink and Honey lake; and Walker, Carson and Truckee on the south, filling respectively Walker, Carson and Pyramid lakes—the latter of which we propose to visit.

—And now, dear readers, who went with

us last year to Tahoe, the Big Trees, Yosemite and the silver minns, please

"Jump into the wagon and we'll all take a ride."

No fear of crowding the Professor. Only tell him plenty of stories and he will gladly walk. And you must allow me the privilege of walking too, to gather and study the plants by the way. See here, before getting out of Sierra valley, what beautiful specimens of the four new *Astragalus*, viz: A. Lemmonii, A. Pulsiferæ, A. Webberi and A. (unnamed), each particularly abundant along the bottom and sides of Beckworth pass, as if the seeds were sown here by the water current surging through here ages ago.

Flora of the Great Basin.

Emerging through this cleft in the high Sierra, and coming into full view of the shimmering basin below, with the snow-tipped Humboldts in the distance, I will leave you to contemplate the scene, while I pick up this desert plum, *Prunus Andersoni*, this worm bush, *Sarcobatus vermiculatus*, the first of the desert plants met with on the down grade.

Here on the floor of the basin, radiant with beauty, grows the only plant Dr. Gray will allow named for him on the western continent, *Grayia polygaloides*. It is a bush two to five feet high, densely crowded with spikes of flat circular pods, half as large as five-cent coins and red as cherries; "neat but not gaudy," is the Doctor's apt description.

A large part of the flora of the basin belongs to the order of *Chenopods*, or the goose-foot family, distinguished by their thick, hairy, succulent leaves, often shiny stems, and the extreme loneliness of the entire order, with the exception of the *Grayia* mentioned. The order most numerous is the one everywhere most abundant, found on every spot where vesicular plants may thrive, the immense order of *Compositæ*, or sun flower. This order comprises about 10,000 species, and forms, according to Humboldt, one-ninth of all the flowering plants of the globe and one-half of its tropical flora.

Chief among this order in the basin is the renowned "sage brush," a name loosely applied to several kinds of plants having the same ashen hue, and found on the great arid plains from the forest-clothed slopes of the Sierra to the bottom lands of the Missouri.

Whether the order or genus, all is modified to conform to the requisites of this hot region; thick leaves to hold the moisture when the sun is high; copious, non-conducting hairs, to prevent exhalation; sharp, forbidding spines, to ward off enemies of the animal kingdom. This spinescent character is most puzzling to the reflecting mind. What need of such protection in a region so desolate, so unfrequented? The rich open prairies and forests of other lands invite population. This arid, seemingly waterless basin is clothed, except where bleak alkali and salt deserts prevail, with dense, thorny, almost impassable sage brush, as if to guard a priceless treasure. And Darwin says it is so. He affirms that here are reservoirs of elements now unfit for use, which the art of the coming man will turn into verdant forests or beautiful fields, as the needs of a teeming population will demand. Corroborative of this theory, most wonderful vegetable growths are now seen in the valley of the Jordan, filled by the devoted Mormon, and in the valley of the Cerson, verdant with alfalfa; both of these valleys immensely changed in value as the result of irrigation skillfully applied and on a large scale. But I must bury you or you will leave me pondering here in the sand.

The first of the valleys between the cross-bars of the gridiron is Long valley, threaded in winter and spring by Long Valley creek, rising near Reno and running north to Honey lake. Passing down it 25 miles we turn eastward through a cattle range enclosed by a fence of matted willows, climb the first ridge and Soda Lake valley is before us. The lake is a yellow pool of salt, alkali and sulphur. Crossing to the second ridge and climbing it, we look over into Winnemucca valley. On the pass at our feet is a beautiful *Scutellaria nana* (Gray), a new species. It maintains its green, robust look by means of reservoirs of plant food stored in its thick, necklace-like, subterranean stems. The next is Warm Spring valley, quite large and important. Through it passes the road from Reno to Snrpriss valley and Fort Bidwell. Passing around a sand mountain, gemmed with rare *Eriogonum*, we ascend an arm of Warm Spring valley, move over a high pass and drop into a valley so walled in with sheltering ridges as to afford a surprisingly large and varied flora.

Every mile of our progress to this point has been marked by decreasing verdure and the appearance of the peculiar ashen, dwarfed, desert plants. But here in this little valley all the species met with on the way are crowded, while hosts of strangers appear. In rapture, I named it for the veteran botanist,

Gray's Valley.

Here in this secluded garden of the great basin is the natural home of the eend and sun-loving plants, too numerous to name—all putting on their gayer apparel and exhaling the richest perfumes, as if to prove the oft quoted lines:

Full many a flower is born to blush unseen
And waste its sweetness on the desert air.

Here flourishes *Tetradymia spinosa*, with strong, hooked prickles; the monster *Thellipodium*, four to six feet high. Up on the hot sand bluffs stands, sentry-like, the scrubby crucifer *Stanleya pinnatifida*, with spikes of yellow flowers 18 inches long, terminating up-

right; white limbs four to six feet high. On the clean eend by our feet nestles the curious *Coldenia nuttallii*, the purple *Conanthus aretioides*, the yellow *Emmenanthe glandulifera*, the sneaked-like *Anisocoma aculea*, and several species of the ever beautiful *Eriogonum*; but most striking of all uprears the rare *Abronia Cruz-Maloe* of Dr. Kellogg, holding at arm's length its large balls of pink flowers. Over the dry watercourse, *Oleome lutea* peers; from the rocks on each hand hang *Pentstemon* and *Arenarias*, while the gorgeous *Eschscholtzia* shows its red eyes between the clefts, and the immortal *Levisia rediviva* on the gravel above espies to notice by creeping to the edge of the precipice.

This plant is well named *rediviva*. Roots gathered nearly two years ago are growing still in their papers despite heavy pressure, illustrating the power with which they are endowed to resist the severities of the basin climate. Deep rooted in the volcanic ashes of yonder heathen glows *Opuntia pulchella*, the prettiest of the *Cacti* family, and that odd little stiff-leaved, crimson *Oxytheca perfoliata*. Under the spiny hushes of *Bignonia graveolens* carpeting the whole valley, are seen a few plants of *Pectocarya pentellata* strayed away from the coast, and *Blitum carinatum*, only found before in Australia.

(The uninitiated reader will please pardon these hard words, for we are on a botanical excursion and this is Gray's valley. I have not afflicted you yet with *Cosmanthoides infundibuliformis*, nor *Platyachne integrifolia*, much less *Gliesbreghtia grandiflora*, so give me credit for a little cherity.)

But we must not linger in this flowery vale. The dry water course along which our road passes grows wide and precipitous. Through the gorge ahead appear the dim peaks of the Humboldt. A great valley must be near, and our map tells us it contains one of the goals of our long journey—

Pyramid Lake.

From a high bluff on the west side we come into full view of this vast, gloomy, awe-inspiring sea, low sunk in its long, sandy, volcanic bed. First, before even a sweeping glance, taking in the whole grand scene, the eye rests enchanted upon a pair of objects directly in front. The heart throbs violently. You can scarce believe your eyes. You must be transported to Egypt, for there are the *Pyramids*! The nearest, square-sided and true as if hewn with masonic skill, towers up 300 feet from the apparent center of the lashing waves. The other completes the Egyptian picture by presenting a flat-topped area, which a nearer view reveals white with thousands of pelicans. It is these wonderful symmetrical monuments which give the lake its name. It could bear no other. Even the Pinte name, *Pe-nock-thou*, refers to the pyramids.

Pinte Reservation.

Touching the south end of Pyramid lake is a small, green, pear-shaped mass of what appears to be willows. A journey of 30 miles towards it would show a large forest of cottonwoods, carpeted with grass and flowers fostered to a rank growth by the sediment brought down from Tahoe lake and the valleys between by the Truckee river, which pours its torrent ceaselessly into this engulfiog, but never disgorge, sea. This rich bottom land—the delta of the Truckee—with a large region round, including the whole of Pyramid lake and its shore for a mile inland, is reserved by the government for the occupation of the Pinte nation. The agency buildings are built in the shady grove, and hundreds of "wickens" are scattered among the trees. Willow fences enclose the richest lands, and the Indian is instructed to till them, but Mr. Pinte finds it too much like work. So he lives mainly upon trout caught in the lake, rabbits hunted in the sage brush and supplies dispensed from the agency. The number of Indians differs constantly, owing to their migrating habits, from only a hundred to often a thousand. Excessively fond of gambling and whisky, they are fast perishing away.

As we proceed along the bluff on the west side of the lake, going northward, more wonders appear.

The Sunken City.

From behind a jutting sand dune an assemblage of splintered rocks of similar formation to the pyramids rise abruptly from the sea, instantly suggesting a sunken city. A day's travel towards them increase their size to that of immense fortifications, battered and torn into all manner of shapes. You can count over 50 of those rocky islets standing there in the sea, so black, so splintered, so suggestive of human agencies, that you rub your eyes and think in order to realize that you are not in Italy. And this resemblance to human structures is heightened by the entire absence of anything like them in all the enclosing mountains. They seem foreign to the country. The far Eastern shore, dimly seen across the dark sea, looks a bare, sandy plain, stretching away to nearly as bare and brown mountains that limit the view. Not an oasis, not a patch of verdure save scant ribbons of salt-grass that do not deserve the name of meadow, and the cottonwood at the reservation, appears in all the horizon. Can any scene on this continent be more drear? How different, how opposite this lake and its scenery compared with its mother—the matchless sea from which its waters come—the far-off, mountain-supported, forest-rimmed, cloud-curtained, sky-hued Tahoe!

Pyramid Contrasted with Tahoe Lake.

No two objects in nature of the same name,

probably, can present so many contrasts as Tahoe and Pyramid lakes; the one pouring its pure, wholesome waters by the Truckee river into the filthy sink of the other; the one elevated 6,420 feet above sea level into the cool cloud land, the other depressed 3,000 feet into the treeless plain, scorched by the glaring sunlight; the one bordered by bright meadows and dense evergreen forests, the other rimmed by alkali flats and hold reaches of sage brush; the one a source of unmeasured wealth to the cities of Nevada through its forest and meadow products, the other utterly worthless, a horrid incubus resting upon the fair face of the State; the one attracting to its shores on all sides thriving villages occupied by cultivated and happy people, the other presenting a smooth shore-line of 120 miles, broken by only one little grove of cottonwoods, the wretched shelter of a small herd of savage, vanishing Pintes; the one flocked with the white sails of the pleasure boat and striped with the broad trail of the passenger steamer, the other unrelieved through all its expanse save only a few Indian canoes and thousands of homely pelicans riding its turbid waves; the one the far sought resort annually of hundreds of invalids whom but its miraculous climate can restore, the other only visited per force, by the ranchman who must enter this malarious valley in search of roving stock; the one inspiring with the grandest thoughts by its sublime scenery, the other depressing almost to nausea by the monotony of its surroundings; the one raising the soul up to a conception of the might, perfection and benevolence of the Creator, the other tempting the reason to distrust the wisdom of a Being who could have need of any such odious thing in his process of world-making; the one a glimpse of Paradise, the other a vision of Hades; the one a jewel, the other its dross; the one light, the other gloom;—life—death!

[To be Continued.]

The Wallace & Ferguson Mine.

A correspondent at Sheep Ranch furnishes the *Calaveras Chronicle* with the following history and description of the celebrated Wallace & Ferguson mine, located at that place. It will be read with interest: As I have been at the Sheep Ranch of late I thought I would drop you a few lines in regard to the Wallace & Ferguson claim.

It is 1,600 feet in length; average width, from 16 to 18 inches. The course of the ledge is nearly east and west. The claim was first located by Messrs. Ferguson & Smith, eight years ago, as an extension of the McNeir claim. At that time the nearest mill was at El Dorado, seven miles. For illustration I will say they commenced in the woods end darkness, but Ferguson, satisfied with the prospect he had, knew that daylight was ahead, and that he would in time step into it by close attention and economy in the management of prospecting the claim. The Smiths sold out five years ago to Mr. Wallace, a man who pays strict attention to business and always keeps on the safe side. Now for a further description of claim. It has been worked 1,600 feet in length, to a depth of 100 feet on an average, which paid, from top down, from \$60 to \$70 per ton. The lowest yield of a week's run of mill was \$33 per ton. They now have a 50-horse power engine at work. Mr. Trump, of San Andreas, planned and built their hoisting works, which, as far as I am a judge, are as perfect a piece of work as can be. They are now sinking the shaft below the old works, contemplating reaching a depth of 125 feet. It was 95 feet deep when I left, and as they go down the rock grows richer and richer—good for \$100 per ton. This work is near the center of the claim. Think of 1,600 feet in length, 18 inches thick, 125 feet deep and good for \$100 per ton—which is a certainty. The claim wants no blowing. The yield of gold it has given for years tells its own story. They have a five-stamp battery or mill, which is kept in constant motion.

The "Ranch" has two stores, kept by Messrs. Hughes and Dughi, 13 families and quite a number of unmarried men.

CALIFORNIA CAR WHEELS.—A set of wheels were taken from beneath the baggage car of the California and Oregon express train at Sacramento, Tuesday, which had traveled in daily use 91,800 miles, and they were not worn out then, but had become loose on the axle. A few weeks ago a set was taken from beneath the same car that had traveled about 80,000 miles, and there are yet remaining under the car two more sets, put in use at the same time as those mentioned above, and yet so little worn that they probably will not have to be removed for months. All of the wheels were cast at the railroad foundry in Sacramento, and reflect much credit upon that institution.

N. P. R. R.—The engineer corps of the North Pacific Coast railroad company is now operating between Freestone and Valley Ford, surveying the original location. About the 1st of March a grading force will be put on that portion of the route, and the road bed will be completed to Freestone in time for the iron, which is expected to arrive about the 1st of July. The road will be completed through Dutch Bill canon and down Russian river to Duncan's Mill by the 1st of November.

EGYPTIAN IRRIGATING APPLIANCES.—It is stated that 30,000 *sakias*, or water wheels, and 70,000 *shadoofs* (which is a long pole placed on an upright post, with a bucket at one end and a weight at the other) are constantly at work in Egypt Proper.

MECHANICAL PROGRESS.

A New Photographic Printing Process.

It is well known that a layer of gelatin containing bichromate of potash, or the so-called bichromate of gelatin, possesses the property of becoming insoluble by the influence of light. If a glass plate is covered with such a layer and exposed to the sun or to daylight under a negative, the places exposed to the light become insoluble, and those protected or shaded will remain soluble, and may afterward be water-soaked, while the insoluble portions will remain dry, and thus having the advantage of taking up the oily printing ink, such a plate can be used as a lithographic stone and printed from in a lithographic press; this is one of the known methods of photo-lithography. Other modes have been invented, intended to prepare plates in such a way that they become similar to wood-cuts, and may be printed on a common press. Some of them are now in use in this country, but the simplest and best is perhaps the method of Despaquis in France, lately published, and chiefly intended for manufacturing purposes. Instead of a glass plate, he uses a corresponding large belt of linen, on which he places the layer of bichromate of gelatin, develops the image in the usual way, removing that part of the gelatin which has remained insoluble as much as possible, he then sews the ends of the belt together, and stretches it between two pulleys, while by the addition of a little glycerine the whole is kept flexible and prevented from drying hard. On one of these pulleys, revolving by steam power, the belt is inked by an inking roller; by the other pulley the pressure is produced on an endless strip of paper or other material which thus receives a continually repeating impression of what there is on the belt. It is proposed to accomplish in this way the reproduction of photographs in a cheaper way than thus far has been possible by any other method, while the use of the principle to print new patterns of calicoes, wall-paper, etc., forms another new industrial novelty.—*Manufacturer and Builder.*

Covering for Boilers and Steam Pipes.

As much inquiry is being made for the best non-conducting substances for covering steam boilers, pipes, etc., in addition to those already given we add the following: The German *Journal of Wooden Manufacturers* suggests that where the material is convenient mix fuller's earth, that has been used and collected in sinks for this purpose, as well as to prevent the filling of streams, with fully the same quantity of coal ashes, and add to the paste mass as much calf's hair as it will take up. Before laying it on add one-eighth its quantity of calcined gypsum, and lay it on in thin coats. If the first layer does not adhere well, unused fuller's earth may be used for it.

Mr. Krupp, of Prussia, has applied largely, at his steel works in Essen, iron furnace slag with highly satisfactory results. It is incombustible, and altogether appears well adapted for its purpose as a non-conductor of heat. It is made at the large furnaces for converting the ironstone into pig iron, where the slag is kept continually running out at a small opening, about one inch in diameter. From thence it travels through an open spout, and falls from the end about 30 inches, at which point a pipe coming from the blast chamber is fixed. The rush of cold air, coming in contact with the melted slag, drives it into thousands of fine hair-like threads, resembling fine spun glass, or asbestos. Although it has much the appearance of cotton wool, the fine points of the fibers, if much handled, pierce the skin like so many fine needles. The material is being introduced in England.

Utilizing Coal Dust.

Three or four months ago the experiment was first tried of using coal dirt, in place of coal, in raising steam for the purpose of pumping water into the reservoir of the Philadelphia and Reading company, North Sixth street. It proved a complete success. From three to four tons of coal had been used each 24 hours, and with the same quantity of coal dirt, even more steam was raised than before.

Coal dirt was next used under the two cylinder boilers in the iron car shop of the railroad company, south of Chestnut street, and it did admirably. By using a quantity of dirt equal to the amount of coal formerly consumed, more steam was raised than before.

The large tubular boilers in the machine shop, between Chestnut and Franklin, are now also supplied with coal dirt, and it answers the purpose, though, owing to the tubes, the draft is not as strong as that in the cylinder boilers, where such a powerful draft can be obtained that the flame will strike out of the top of the smoke stack. Under all these boilers the very best anthracite coal was formerly used.

An *Eagle* reporter has been informed that it is the intention of the railroad company to use coal dirt wherever they have stationary engines, and it is being tried in one of the locomotives on the railroad, with a fair prospect of success. In burning coal dirt, steam is introduced into the furnace through the grate. The improvement is said to be the invention of the general superintendent, J. E. Wooten.—*Reading Eagle.*

Cutting Steel With Soft Metal Discs.

Prof. B. S. Hedrick, of Washington, read a paper at the Detroit meeting of the American Association for the Advancement of Science, explanatory of the mode and the essential character of the operation by which soft iron is made to cut hard steel. The development of heat by friction has been known for ages. A more recent discovery is that the operations of rolling and rubbing have the effect of changing the molecular structure of iron and steel, toughening and rendering more compact even cold iron and hardening as well as softening steel. Mr. Jacob Reese, of Pittsburg, Pa., had been endeavoring to construct a machine to cut hardened cold steel. He accomplished it at length by means of a soft iron disc rotating at high velocity. With low speed this would not cut at all; but when running at about 25,000 feet per minute the disc cut through steel rapidly, giving out an immense cascade of sparks in the operation. It was found on examining the debris beneath the disc that the particles of steel were not simply rubbed off. They were welded together in a pyramid like a stalactite or the snow icicles formed on the top of Mount Washington. Prof. H-drick ascertained that real fusion had taken place among the particles of steel. The disc is very little heated, but the steel is actually melted and drops down. Yet the heat on each side of the cut is not heated enough to draw the temper or oxidize the metal. Solid bars of steel of two inches or three inches in diameter are thus cut through in as many minutes. The soft metal disc is about 42 inches in diameter. The naked hand may be passed through the jet or stream of flying sparks during the operation without being burned, since the particles of melted metal are in the condition known as the spheroidal state.

NEW EXPLOSIVES.—A new explosive compound has been introduced in Europe, and the name of "Vigoris" has been given it. It is formed of 25 to 50 per cent. of nitroline, nitrate of potash 15 to 25 per cent., chlorate of potash 10 to 30 per cent., and 15 to 35 per cent. of cellulose. Another explosive recently invented by Trautzschler Falkenstein, and apparently made of woody fiber prepared with nitro glycerine, has been recently tested in various mines in Upper Silesia. The results were on the whole not unfavorable, but the action was not always regular. The substance has not (as was at first claimed for it by the inventor) five times the force of an equal weight of ordinary black blasting powder, and even four times was doubtful; but a three-fold force may be readily conceded. The advantages of the new agent are, less danger, as it does not explode on contact with open fire, and is but difficultly exploded by friction or concussion; and the fact that, to effect its explosion in a blast hole, the strand match may be used. The powder is very light, and in the loose state burns very slowly. A manufactory for the new agent has been established in Kietzsch. This explosive, it will be seen, is similar to giant powder—a vegetable fiber instead of a mineral powder being employed as a carrier for the nitro-glycerine.

LOCK WELD ANVILS.—Messrs. B. W. Baldwin & Co., of Pittsburg, have lately begun the manufacture of an anvil that, according to *Iron Age*, promises to rival those of English make. The anvil is wrought iron with steel face, but the special improvement consists in the lock weld anvil being generally made in two parts, and these welded together with a broad, flat weld. This process of welding often proves deficient, the fiber of the iron not being joined, but fiber placed on top of fiber, not a weld but a cement of the two parts, which, when the anvil is put to a severe test, too often breaks in the shank, becoming worthless. The American anvil works make the lock weld or wedge shape. In the bottom of the anvil there is a deep groove, the top has a V shaped projection that fits in the corresponding groove bottom. When the weld is made the fiber meets, interlocks and forms the most perfect weld that can be made with iron. Another improvement in the American anvil is, the top block is made from plates welded together and placed on edge, not flat as is customary with other manufacturers. The face of the anvil is made from a thick steel plate of the best quality.

THE NUMBER OF BESSEMER STEEL WORKS IN THE WORLD.—Great Britain has now 21 Bessemer steel works, with 105 converters; Prussia, 14, with 61 converters; Austria, 12, with 30 converters; Bavaria, two, with four converters; Saxony, one, with four converters; Alsace, one, with two converters; France, eight, with 25 converters; and the United States, 10, with 20 converters. These totals make up an aggregate of 71 works, with 251 converters, representing an annual productive power of 2,500,000 tons.

THE FUTURE OF PETROLEUM.—Although petroleum is not iron, it is so closely connected with it that its ups and downs have a very marked effect upon certain forms of iron and its manufactures. Tubing pipe, steel for tools, engines, boilers, pumps, tank iron, rivets, hoops, all enter largely into producing, refining and transporting carbon oil; in fact the consumption for this purpose demands the larger part produced of some classes mentioned. This fact gives the iron trade an interest in the future of this product.

SCIENTIFIC PROGRESS.

How the Sky Looks to "The Man in the Moon."

If there could be such a thing as "a man in the moon" he would see such "sights" in the heavens as we, upon the earth, have very little idea of. A late writer in the *British Quarterly* has been indulging a little in this kind of imagination, and this is the way he puts it:

"At last, however, night sets in. Gradually it comes, after the sun has gathered up his smiting beams and gone down to rest. At all once we are plunged into comparative obscurity, for again there is no twilight to stay the steps of departing day. But looking up into the sky we behold a vast orb which pours down a milder and more beneficent splendor than the great lord of the system. It is such a moon as we terrestrials cannot boast, for it is not less than 13 times as large and luminous as our own. There it hangs in the firmament without apparent change of place, as if 'fixed in its everlasting seat.'

"But not without change of surface. For this great globe is a painted panorama, and, turning around majestically on its axis, presents oceans and continents in grand succession. As Europe and Africa, looking the Mediterranean in their embrace, roll away to the right, the stormy Atlantio offers its waters to view, and then the two Americas, with their huge forests and vast prairies, pass under inspection. Then the grand basin of the Pacific, lit up with island fires, meets the gazer's eye, and, as this glides over the scene, the eastern rim of Asia and the upper portion of Australia sail into sight. The Indian ocean, and afterward the Arabian sea, spread themselves out in their subdued splendor, and thus in 24 hours the great rotundity we tread turns its pictured countenance to the moon, and gradually repays the listening innuants by repeating to the best of its ability the story of its birth.

"Nor is the sky less marvellous in another respect. For the absence of any atmospheric diffusion of light permits the constellations to shine out with a distinctness which is never paralleled on earth. They glitter like diamond points set in a firmament of ebony. Stars and clusters which we never see with the naked eye, flock into view and crowd the lunar heavens."

HOW PLANTS ABSORB NITROGEN.—Of late there have been some remarkable discoveries in regard to the manner in which plants take in the nitrogen which they contain. It was thought to be certain they did not absorb it through the leaves from the atmosphere; but Mr. Darwin has shown, in regard to insectivorous plants, that these, at least, do. And he has further shown that some plants, with glandular hairs, take in nitrogen through them, besides making it probable that to supply the plant with nitrogen is the office, in a general way, of all glandular hairs. Since that time Dr. Gilbert, of the celebrated firm of Lawes & Gilbert, agricultural chemists of England, has published a paper on the source of nitrogen in some fungi. Mushrooms in general abound in nitrogen; and, as they appear so often in immediate connection with some kinds of nitrogenous manure, nothing was easier than to infer that the mushroom family fed on manure. But Dr. Gilbert's experiments show not only that some fungi of this class grew in soil entirely deficient in nitrogen; but that the health and vigor of these mushrooms were just in proportion to the absence of the nitrogen from the soil. It now becomes an interesting question as to how fungi obtain their nitrogen, and the solution will probably be, as in the case of Mr. Darwin's insectivorous plants, that they obtain it from the atmosphere.—*Ex.*

A THOUGHT ON ASTRONOMY.—Other stars, like our sun, undoubtedly started as vaporous masses, and have thrown off planets in contracting. The inference may seem a bold one, but it after all involves no other assumption than that of the continuity of natural phenomena. It is not likely, therefore, that the solar system will forever be left to itself. Stars which strongly gravitate towards each other, while moving through a perennially resisting medium, must in time be drawn together. The collision of our extinct sun with one of the Pleiades, after this manner, would very likely suffice to generate even a grander nebula than the one with which we started. Possibly the entire galactic system may, in an inconceivably remote future, remodel itself in this way; and possibly the nebula from which our own group of planets has been formed, may have owed its origin to the disintegration of systems which had accomplished their career in the depth of the bygone eternity.

SCIENTIFIC PROGRESS.—We live in an age of progress and discovery; theories that were at first entertained as doubts have been developed into facts. We see on every hand the indications of advancement; one discovery culminates in another; each generation furnishes its idols of genius; the man of science whose knowledge is power points out the results of research for the universal welfare; facts that are startling are constantly met with in this higher state of civilization; scientists that were at first looked on as mad enthusiasts and fit subjects for scorn and contempt, are now recognized as benefactors to the human race.

Bacteria Found in the Perspiration of Man.

Dr. Eberth, of Zurich, Switzerland, has found, says the *Medical Record*, by the aid of the microscope, in the sweat of the face some corpuscles which he considered as bacteria. This view became confirmed when he examined the axilla, breast, and inner side of the thigh of several persons in a state of perspiration. The sweat of these parts contained nearly always enormous numbers of bacteria. In most cases they originated from minute bodies found upon the hairs in the mentioned regions, forming little nodules on them, and giving them a grayish or a brick color. They were recognized by the author as accumulations of micrococci. They may rapidly increase in number, are smaller than diphtherial micrococci, and are nearly indifferently to re-agents (concentrated acids, alkalies, alcohol, ether, chloroform). Iodine colors them yellow. The vegetation of bacteria on the hairs may be observed in cases where they are changed already, beginning in places which have clefts between their cells. The vegetation occupies large spaces, especially in the direction of the longest diameter of the hair.

Dr. Eberth observed a mycelium and micrococci, and thinks that the latter are the fruits of the former. Other investigators observed colored sweat, red and blue, which contained micrococci. It was difficult to decide in these cases if the coloring matter was adherent to the micrococci, or if it was a product of the vegetation.

Interesting Mineral Specimens.

Henry S. Poole, Government Inspector of Mines for Nova Scotia, says that in the collection of minerals to be sent to the Centennial exhibition, from Nova Scotia, there is a specimen of lead ore which shows that the mineral has infiltrated the tissue of some red-like plant of the carboniferous age. It is from the surface soil near Arisaig Pier. No pieces have been found *in situ*. Associated with the fragments discovered are others mineralized by iron pyrites, somewhat similar to those found in the shaly portions of coal seams. Galena is known in other parts of the world to appear in coal, but, as far as the writer knows, never before as a mineralizing agent of vegetable structure.

A further interesting discovery of galena was made at Port Hood, Cape Breton, where a small vein of calcite, containing massive crystals of galena, was found in the sandstone lying between two seams of coal, but no specimens similar to those of Arisaig were found. As they are possibly new, and consequently of interest, this notice has been submitted at the suggestion of Mr. Trautwine.

Whether new or not, such specimens are of some value as confirming the theory of the aqueous origin of some mineral veins, for although the blast furnace has proved that galena can be volatilized by heat and recrystallized on cooling, the finding of galena in places where it could not possibly have been exposed to a high temperature requires some other agent than heat to account for its aggregation and deposition, and suggests the universal medium of solution, water, as the agent.

IMPORTANT TO BOTANISTS.—A French gentleman, M. Boudin, has discovered that if freshly gathered plants are spread out between sheets of filtering paper in the usual herbarium manner, and then heated between two bricks in an oven for two or three hours at about 150 deg. Fah., they will be perfectly and permanently preserved without impairment of the most delicate colors. The process is rendered more rapid and certain if the layer of filtering paper next the flowers be changed after about an hour.

PHOTOGRAPHY.—On the 2d of October, 1839, Daguerre took his first picture in public—before many of the members of the Society of Fine Arts. It represented that part of the Tuilleries known as the Quai Voltaire, on the other bank of the Seine. It has been presented to the French Conservatory as an interesting record of art and of Paris of the past. The Tuilleries is in ashes, and although but 36 years have passed, changes have come so quickly in art that the younger generation scarcely knows what Daguerre means.

VERY MINUTE ANIMALS.—When Lieutenant Berryman was sounding the Atlantic, preparatory to laying the ocean cable, the quill at the end of the sounding-line brought up mud which, on being dried, became a powder so fine that on rubbing it between the thumb and finger it disappeared in the crevices of the skin. On placing this dust under the microscope, it was discovered to consist of millions of shells, each of which had a living animal.

A NEW MINERAL.—Prof. J. W. Mallett describes in the *Journal of the Chemical Society* a new molybdo-oxide of lead, from Mexico, for which he proposes the name of achrematite. The mineral is compact, and here and there indistinctly crystalline. Color, liver brown; luster, between resinous and adamantine; specific gravity, 6.17, hardness, 3.5.

THE ACTION OF SALIVA.—M. Petit recently communicated to the Société de Pharmacie of Paris the results of his experiments on saliva. He had found that one gramme of tyline had the power of dissolving from 10,000 to 20,000 grams of starch, producing a quantity of sugar varying between 3,500 and 7,000 grams.

Compiled every Thursday from Advertisements in the Mining and Scientific Press and other S. F. Journals.]

It is a peculiar feature of this market that the Bonanza stocks have not advanced near in proportion to the other stocks. Many causes are assigned for this, but upon an excited market, like the present, they must be accepted with a certain grain of allowance. A curious feature of the market was the very rapid advance of Mexican, while its usual leader, Ophir, didn't make a rise at all in proportion. On Wednesday the open board session began with a quick upward movement, which was immediately followed by a flood of stock being dumped into the market, which, being in a sensitive state, caused by the decline of Tuesday, was unable to stand the pressure. Numerous persons who had bought for a turn on Tuesday, thinking the bottom had been touched, became nervous and dropped their stock upon the impulse of the moment.

Although the time for transacting business in the Board was extended this week, the brokers couldn't get through half the list. On Tuesday the time for transactions was again extended to one hour and a half, and the number of stocks called was still less than those of Monday, consisting only of the first 18 on the list. The business done in each stock was very large, and though prices averaged lower than those brought at the informal session, it goes to prove there were an unusual number of orders in the hands of brokers. The cause of the extreme rise of Monday is said to have been the large number of orders accumulated during Friday, Saturday and Sunday. The telegraph wires beginning to work on Saturday after the regular business hours were over, transactions of only a limited nature could then be filed and were necessarily laid over until Monday, when all coming in together upon an extremely sensitive market brought about the result which followed.

This has been a most eventful week for mining stocks. The market has been "booming," although as we write (Thursday evening) there are signs of a relapse back nearly to former prices. This has been the longest continued rising market for a very long time. Tuesday was the most exciting day witnessed in the stock market since the great excitement of December and January, 1874-75, while the advances and declines in many of the stocks would compare favorably to the rapid fluctuations of those days. A good many think that the large market promised is close at hand, and that the uncovering of new ore deposits, and the large yield of the Con. Virginia, and the promises that California is to start in crushing and begin the earning of dividends within 30 days, indicate that such is the disposition of those who control the market, notwithstanding the rumors that Flood & O'Brien are striving to keep the market down so as to get control of those mines that are threatening to expose developments that may rival the bonanza of the California and Con. Virginia.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior in proximity to the mines mentioned.

California.

ALAMEDA.

NEW COAL DISCOVERY.—*Livermore Enterprise*, March 4: Mr. Jenkins Richards some time since started a tunnel about half a mile above the Livermore coal mine in hopes of striking a new vein, and after running 400 feet struck a vein of coal six feet in width, and ran upwards of 45 feet from the surface. The sample sent us shows a clear bituminous coal, and the approach in splendid condition. Mr. Richards expects to have a sample supply of coal before the public within the next two weeks. We anticipate a very prosperous discovery, and we shall take pains to visit and inspect the mine before speaking further.

ALPINE.

EXCHQUER.—*Alpine Chronicle*, Feb. 26: Sinking of another 100 feet in the 300-ft shaft will commence next week. Good ore is to be mined to the mill. The mill is being put in order as fast as possible, and will commence crushing within the next three weeks. Foreman Beach has orders to increase the force as he can make available.

SIGNIFICANT.—Thirteen of the men working at the Exchequer mine applied to Manager Chalmers, last week, for Exchequer stock. The manager has written to the board of directors that the stock is for sale. That the practical miners in the employ of this company desire to invest their hard earnings in its mine, is a good evidence of its riches.

AMADOR.

CONTRACT LET.—*Amador Ledger*, March 4: We mentioned in our issue of two weeks ago that a quartz ledge had been uncovered on the hill overlooking Sutter creek, facing the Amador Consolidated mine, on the opposite side of the road. We have now to state that a week ago a contract was let to sink 100 feet on this property. The opinion is held by many mining experts that the main ledge extends in this direction, and from its proximity to the Amador Consolidated, it is confidently believed that if a mine is developed in this locality it will be a rich one.

ONIDA MINE.—Taking advantage of the scarcity of fuel and the consequent temporary stoppage of the mill, prospecting operations are being pushed forward on this mine. A new level is being opened at a depth of 140 feet. The east crosscut in this level has already entered the black slate which is always found adjoining the ledge. It will strike the ore body this week on the north end, which has always been found the richest part of the lead. The 1000-ft level is being pushed south into the hill separating the Onida from the Kennedy—a locality which has never been explored. Altogether, the mine is being prepared for vigorous work through the coming summer.

STRUCK IT RICH.—Recently, Richard Stoken, while prospecting near the Pioneer claim, about four miles above Volcano, struck a small quartz vein, some six or eight inches wide. Some of the specimens were exceedingly rich in free gold, and he was induced to crush a few pounds of the rock in a mortar, realizing that he had struck it rich. He then commenced washing the dirt after the water. After working for a few days with a pan, he took out \$200 in coarse gold. He has evidently happened upon one of those rich pockets, which seem to abound in that part of the country.

ANOTHER FIND.—John Brown and George Troop lately discovered a quartz lead some four miles beyond Volcano. The vein ranges from eight to 18 inches in width, and is about 100 feet long. The ore is very rich, and the owners have put a tunnel to the hill, and are now sinking a shaft to connect with the tunnel. The mining interest in that particular section has picked up considerably of late.

BUTTE.

GOLD.—*Oroville Mercury*, March 3: On Saturday last week the Spring Valley mine, near Cherokee, sent to San Francisco three bars of gold that were worth \$61,400. A few days previous the same company sent about \$12,000 worth of gold, making in the week \$73,000, all of which was the result of less than 30 days' run. This is not the full amount of the run, as the company is still engaged in closing up, but is what has been taken from the boxes that had been cleaned on Thursday of last week. With such good luck, it is hard to be convinced that the mines are "played out," as Mr. Berry and some of his conspirators would have us believe.

KERN.

RICH DEVELOPMENTS.—*Southern Californian*, March 4: The Consolidated Bunnell company have opened a new tunnel on their lead on their claim on the mountain, one mile southwest from the Bunnell tunnel, which promises rich developments. The lead is 22 feet in width, and assays as well, if not better, than that in the original at Bunnell. John A. Harley, of San Francisco, principal owner in the mine, has forwarded the machinery for the mill, and expects to have it in running order in ninety days. There are now 40 men at work on the mine and mill. We had the pleasure of meeting Mr. Harley last week, and he indicates abundant spirit for the enterprise. There will be no lack of water to effect the process, the rich deposits already visible from the surface. John A. Harley, the proprietor of the Winnemucca reduction works of Nevada, has the superintendence of the construction of the mill and furnaces. The mine has been examined by experts sent from San Francisco, and some of the most celebrated mine owners of Nevada are arranging for interests in the new discovery. Mr. Harley proceeded to San Francisco and secured the necessary money for the expedition, and nothing will be spared to advance the enterprise, the great value of which is assured by more recent assays of the ore and reports of mining experts who have completed their examination.

NEVADA.

MOORE'S FLAT.—*Cor. Nevada Transcript*, March 5: Once again we are enjoying the blessings of a blockaded road and a scarcity of provisions. Our road is blocked for five miles with a depth of from four to six feet of snow, and at present writing the snow is coming down with a vengeance. The Harley shaft has again been substituted for the mail bag, and the stage comes in on snow shoes. The stage companies, who have been running a little water to keep their mines from slush. Outside of this, nothing is being done in the way of mining. Notwithstanding the severity of the winter, our miners have bright prospects ahead, and the amount of sickness that will be sent down the Yuba from here next summer will make the Grangers swear. We have no coal, salt meat, or greens of any kind in our market, and a snow shoe train is sent twice a week for supplies to Bloomfield. This is the first winter our merchants have been caught out, but they won't be caught napping next fall.

OR. HILL.—*Foothill Tidings*, March 4: The last 20 days' run of this mine and mill gave over 600 ounces of gold from the plates and enough sulphurets to make the yield worth something over \$11,000; and the host of it

is, the pay chute improves as they go southerly. No wonder Omaha stock took an upward about lately and that other mines in the vicinity are held and esteemed "glit edges," particularly those on the same side south.

NEW YORK HILL.—We hear very few raba rumors from this mine, one of which is that they have three pay chutes now and are taking out good mill rock from all.

PLACER.

Mining Materials.—*Placer Herald*, Mar. 4: Recent developments have given great impetus to the mining interests in this part of the county, and in Ophir district especially. The Orator, which belongs to the St. Patrick company, is yet, and likely for some time to remain, the banner mine of this district, and perhaps without a superior in the State. This mine is under the superintendence of John A. Townsend, a miner of about 30 years' practical experience, who doubtless knows as much about quartz mining as any other man in California. The rock from the Orator has been yielding well for some time, as may be better realized when it is known that with all the extensive improvements recently made, the company is entirely out of debt, and has ample means in the treasury for all immediate purposes. Mr. Townsend was to make his monthly report last Thursday, and the indications were that it would be a very good one, though at this writing we have not the returns.

The Kirkland mining company, comprised of Scotch capitalists, is just entering on an extensive quartz mining enterprise. All their works are under the supervision of F. R. J. Dixon, an old and experienced quartz miner. On the Kirkland claim they have recently erected new hoisting works. The shaft, which is 410 in the clear, and is as well timbered as any we ever saw, is now down about 70 feet. It is the intention of the company to sink the shaft on this mine 600 feet deep without stopping. As far as they have gone the rock prospects well, and the general opinion is that when they get to the 600 ft level, or even before, they will find themselves in possession of a fine paying mine.

The Good Friday, which has for some time past been yielding rich ore, has recently been purchased by the Kirkland company for \$15,000, and will be worked by that company hereafter for all its worth. The St. Lawrence mill, 13 stamps, has been leased by this company, with the right to purchase, perhaps, yet, and the work on the Kirkland claim they have recently erected new hoisting works. The shaft, which is 410 in the clear, and is as well timbered as any we ever saw, is now down about 70 feet. It is the intention of the company to sink the shaft on this mine 600 feet deep without stopping. As far as they have gone the rock prospects well, and the general opinion is that when they get to the 600 ft level, or even before, they will find themselves in possession of a fine paying mine.

The Julian, in Newcastle district, though we did not visit it, we learn is running steadily on paying ore.

Dutch Flat.—*Dutch Flat Forum*, March 2: Twelve miles above Dutch Flat are located several paying and prosperous mines, known as drift diggings. The first claim is known as the Dry Creek claim, owned by E. W. & B. H. Bartlett. In this mine they have a bedrock tunnel 110 feet long, where they strike the bedrock gravel, and from this point they are in 150 feet and are now working nearly 100 feet on the east side, and about 45 feet from the surface, on cases which are run by water power. Two men picked up in one day \$14 in chunks, and in the week over \$90. The prospects in this claim are flattering and promise good results. About 700 feet down the river from the above named claim is one owned by John Whipple & Co. No dirt as yet has been taken out by this company. They are running a bedrock tunnel 100 feet long, and are now working about 45 feet from the surface, on cases which are run by water power. Two men picked up in one day \$14 in chunks, and in the week over \$90. The prospects in this claim are flattering and promise good results. About 700 feet down the river from the above named claim is one owned by John Whipple & Co. No dirt as yet has been taken out by this company. They are running a bedrock tunnel 100 feet long, and are now working about 45 feet from the surface, on cases which are run by water power. Two men picked up in one day \$14 in chunks, and in the week over \$90. The prospects in this claim are flattering and promise good results. About 700 feet down the river from the above named claim is one owned by John Whipple & Co. No dirt as yet has been taken out by this company. They are running a bedrock tunnel 100 feet long, and are now working about 45 feet from the surface, on cases which are run by water power. Two men picked up in one day \$14 in chunks, and in the week over \$90. The prospects in this claim are flattering and promise good results. About 700 feet down the river from the above named claim is one owned by John Whipple & Co. No dirt as yet has been taken out by this company. They are running a bedrock tunnel 100 feet long, and are now working about 45 feet from the surface, on cases which are run by water power. Two men picked up in one day \$14 in chunks, and in the week over \$90. The prospects in this claim are flattering and promise good results. About 700 feet down the river from the above named claim is one owned by John Whipple & Co. No dirt as yet has been taken out by this company. They are running a bedrock tunnel 100 feet long, and are now working about 45 feet from the surface, on cases which are run by water power. Two men picked up in one day \$14 in chunks, and in the week over \$90. The prospects in this claim are flattering and promise good results. About 700 feet down the river from the above named claim is one owned by John Whipple & Co. No dirt as yet has been taken out by this company. They are running a bedrock tunnel 100 feet long, and are now working about 45 feet from the surface, on cases which are run by water power. Two men picked up in one day \$14 in chunks, and in the week over \$90. The prospects in this claim are flattering and promise good results. About 700 feet down the river from the above named claim is one owned by John Whipple & Co. No dirt as yet has been taken out by this company. They are running a bedrock tunnel 100 feet long, and are now working about 45 feet from the surface, on cases which are run by water power. MISCELLANEOUS.

Scientific and Practical Ballooning.

Ballooning owes its origin to the discovery, about 1780, of hydrogen gas, by Cavendish, in England, and its extraordinary lightness. The first experiments to prove its levity were made by inclosing small quantities of the gas in airtight bags and allowing them to ascend into the upper regions of the atmosphere. Weights were attached to these bags to show the lifting power of the gas. Cavallo, the electrician, subsequently experimented in the same way in 1782. In 1783 the Montgolfier brothers, of Paris, repeated these experiments on a larger scale, and gave the first impulse to ballooning proper. They attached a car to a balloon, in which small animals were placed.

The first human being to ascend was M. Pelatre, who ventured up to a height of about 100 feet, with a rope attached to the car, by which it was drawn back. The same gentleman, accompanied with a friend, soon afterwards made an ascension to a height of 3,000 feet, descending at a point about five miles distant. From this time the art of ballooning made rapid progress.

It was at once made subservient to purposes of meteorology and physics, and as early as 1794, during the French revolution, was employed by the French as a military machine for making reconnoissances. The officers seat up communicated their observations to the earth by signaling with flags. The French army in Algiers, in 1830, were also provided with balloons. But the most important and really practical use to which that machine has been put was its war uses during the siege of Paris, when that city depended almost entirely upon her balloons and the carrier pigeons which they took away for intercourse with the outer world.

During that memorable siege 65 balloons were sent up from the beleaguered city, carrying in all 91 passengers, 363 pigeons and two and a half million letters. Only five of all this number fell into the hands of the German army, two descended on German territory and were captured, while one disappeared entirely. The fragments of another were found hanging on a tree at Port Natal, in south-eastern Africa, having traversed almost lengthwise across that continent. Where it dropped its unfortunate occupants was never known. All the others, 56 in number, descended safely beyond the radius of the besieging army in France, or upon neutral territory beyond.

The two great physicists, Biot and Gay-Lussac, made two ascents in 1804, to decide some important meteorological questions. They brought back from a height of about 20,000 feet a sample of the air, which was carefully examined and found to be identical in character with that at the surface, a matter, at the time, of considerable importance, as the uniformity of the atmosphere in the upper regions had been called in question.

In 1863, Nader attempted to take photographic maps while floating in the air, but failed.

The great problem of steering balloons has been studied and experimented upon by many of the ablest scientists and mechanists in France and the world, but hitherto with no very satisfactory success. Dupuy, commissioned by the Paris Academy of Sciences in 1872, has probably met with a larger measure of success than any one else, and has probably very nearly reached the ultimate in that direction. He gave his balloon a fish shape, and fitted it with an internal, or secondary balloon, containing more or less air and equal in bulk to one-tenth of the main balloon. The air could be let out of the inner balloon by valves, and drawn in again by an apparatus placed in the car. This arrangement was employed to supersede the use of ballast. He used a propelling screw turned by man-power, instead of steam, which latter was ignored, the strength of eight men being employed instead. His balloon carried in all 14 persons, and traveled about 60 miles. He carried an apparatus by which he was enabled to measure his speed, and also that of the wind. His balloon moved at the rate of about 540 feet per minute, while the wind was moving at the rate of about 2,900. The course of the balloon was at an angle of 12 degrees to the direction of the wind.

In this experiment the problem of steering was solved, although only to a slight degree—sufficient for only a very moderate movement of the air, but quite insufficient for anything like even a moderate breeze. This experiment is quite sufficient to show the inability of any attempt to make ballooning practical for any other purposes than those of war, where the expenses of carrying a messenger to or from a beleaguered city or army are never taken into account.

How They Do It Here.—A Frenchman who has lived in the United States for some years, says: "When they build a railroad in America, the first thing they do is to break ground. This done with great ceremony. Then they break the stockholders. That is done without ceremony."

GERMANY is going to send over here several officers of the mining department, with instructions to study up our mining industries.

Hidden Dangers.

The people of Vienna were thrown into quite a state of excitement soon after the terrible Bremerhaven affair, because a police agent, moved by that terrible catastrophe, had seized and thrown into the Danube three boxes of dynamite which were found in an exposed locality. These boxes, although plainly marked "Dynamite," had been lying in a public building about two years, without any thought of the dangerous character of their contents, until the officials were aroused by the announcement of the above-mentioned catastrophe, when they were hurriedly placed in the hands of a police agent, with the advice that they be at once thrown into the river. This sage advice was quickly carried out; but as attention was drawn to the matter by certain lookers-on, it was suggested that the disposition made of the dangerous compound was not altogether a judicious one, since it placed in jeopardy every sailing craft on the river, as well as the entire city adjacent thereto. Another officer acting on this second thought promptly fished out two of the boxes, but the third eluded his search, and hence the scare lest the missing box should suddenly reveal itself by the destruction of some bridge pier or passing boat.

The above reminds us of a similar instance which came, by hearsay, to the notice of the writer, in connection with a party in this city. The story as told to us is as follows:

At the time of the nitro-glycerine explosion in the rear of the office of Wells, Fargo & Co., on Montgomery street, the party in question had in his possession a small can of that dangerous compound, and, occupying a large lot in the process of being gradually filled up to the grade, thought to rid himself of it by hurrying it in the ground. The matter soon passed out of his mind, but was not long afterwards again called up by reason of some discussion in the city papers growing out of another similar accident. The party in question then commenced a careful search for the place of burial, with the view of its proper destruction, but failed to find the object of his search, and ever since has been very much in the same fix as the distressed citizens of the Austrian capital. Digging foundations for "permanent improvements" on that lot will be a somewhat dangerous operation.

Celluloid.

Celluloid is the name given to a recently devised compound resembling ivory, and which is now used for making of billiard balls, hair brushes, for the manufacture of teeth, and in general, for almost any use to which ivory may be put. This compound is said to be composed of gun-cotton, camphor and other ingredients of uncertain character. It is very innocent and attractive to the eye, but is made up of materials some of which at least we have learned to handle with much caution. The public have been led to believe, however, that when prepared for toilet and other use it is altogether free from danger. Perhaps it is so—so far as actual end violent explosion is concerned; nevertheless, it is asserted that celluloid will readily take fire, and burn with much violence, giving off large amounts of noxious gases, much like the burning of loose dynamite. If this is so, gentlemen who wear celluloid teeth should beware how they put the lighted end of a cigar in their mouths; and ladies who use hair brushes with celluloid handles, should see that they do not bring them too close to the gas-light, for fear of unpleasant consequences. In this age of discovery and invention and adulteration, it is difficult to tell what manner of thing we are either using, eating or drinking.

ARE THEY TO HAVE A TRUE REPUBLIC IN FRANCE?—The result of the recent elections in that country appear to look that way. All the factions there seem to have been defeated. The Republicans appear to be the only power there worthy the name of "party." The Bonapartists, the Legitimists, the Radicals, the Constitutionists and the Conservatives have been ruthlessly slaughtered—have all been pushed to the wall by the Republican masses. Will the leaders of the party, now coming into power, venture to plant themselves upon true republican principles? Are the people of France ready for such a stand? Do the Republican leaders dare to trust the people with a free ballot and a free press? If such a policy can be made successful, a glorious future is open for the French people—a future, the attainment of which will be well worth all the suffering, humiliation and cost of their late terrible conflict with Germany.

EATING QUAILS.—It has often been said and printed that no person could eat a quail, each day, for 30 consecutive days—that, owing to some peculiarity about the flesh of that bird, the attempt at such a gastronomic operation would often lead to such a nauseous loathing as would utterly forbid the entrance to the stomach of even the twentieth bird. But now come a brace of Frenchmen from Louisville, Ky., who put to naught this saying by readily accomplishing the feat; while one of the twain, after swallowing the thirtieth bird, smacked his lips and called for No. 31, which, with four others, was quickly dispatched, when nature rebelled against any further gormandizing.

Business Outlook.

A general stagnation of trade appears to be the case just now in nearly every part of the world. It seems as though all the nations had adopted a policy of a masterly inactivity, or if anything is attempted it is almost always in the way of "selling off." English manufacturers and iron masters are alarmed at the prospect of an almost total annihilation of their American trade. The monetary disturbances in Germany are closing up or running short all her large establishments. There is a moderate degree of activity manifested in France, which, the result of the recent elections will no doubt serve to increase. In our own country financial difficulties and uncertainties seem to hang like a pall over the people, depressing every department of business, without any prospect of immediate relief.

In California almost an equal depression prevails, notwithstanding the universal belief that we are just on the eve of one of the most prosperous business seasons which we have ever met with. But here we are not without hope; all believe in an early and favorable change. The excessive and almost continuous fall of rain which has characterized the present winter has rendered the roads of the interior almost impassable—but little can be done in the way of transportation away from the lines of railroad; merchants in the interior are letting their stocks run to the lowest possible point, while waiting for the roads to become passable again. The farmers, too, are very much behind hand in plowing and seeding, for the same reason. In the meantime the season is advancing and we shall soon reach the time when the rains must cease and the winds and the sun put the roads and fields in order for wheels and plows. When that time does come, San Francisco and California will see one of the brightest seasons ever witnessed here. There will be a large demand for labor; the interior merchants will fill up their depleted stores; the mines, favored with an abundance of water, will pour out their wealth; money will flow back and forth in its accustomed channels, and California will be blessed beyond measure in this our nation's Centennial year.

THE NEWSPAPER BUSINESS.—Perhaps no department of industry has felt the depression which has borne so hard upon the country during the last two years, more seriously than the newspaper business. A carefully kept record shows that during the 12 months preceding November last, over 1,000 newspapers had ceased publication in the United States. It is probable, however, that very few of those papers occupied any field of newspaper literature, where such publications were specially needed; or if they did, the presumption is that there was a lack of either energy or talent equal to the position. A newspaper, properly placed and conducted, is a necessity, not a luxury, and consequently is not dispensed with when hard times overtake the reader. If a paper is really needed in any community, the people will sustain it in spite of hard times, provided the publishers are able to fill the bill.

THE BRITISH COAL INDUSTRY.—The estimate of the amount of coal raised in Great Britain is 130,000,000 tons; of this amount less than 5,000,000 is exported. The loss of life by explosions and other mine accidents is about 1,050 per year, or one death for 106,000 tons of coal raised. These death statistics are collected and preserved, year after year, with much care and dreadful regularity, so that a collier's life may be pretty accurately calculated, according to the amount of coal raised.

BROOMS.—The last outgoing Australian steamer took away a large quantity of brooms—1,134 dozen to Australia and 303 dozen to New Zealand. The broom industry of San Francisco is fast rising to considerable importance, and the manufacturers are building up quite a lucrative business both at home and abroad. It furnishes a large amount of employment on the farm and in the workshop as well.

MAMMOTH BUNCHES OF GRAPES.—Two bunches of grapes were exhibited at the fruit show in Edinburgh, Scotland, last fall, which weighed, respectively, 25 and 26½ pounds. The English papers pronounce them the largest ever produced anywhere. Can our California grape growers go one better than this? If so, we would like to publish the fact for the benefit of our English cousins and the rest of mankind.

THERE are 1,066 manufactories of iron, gold, silver, brass, tinware, lumber, leather, fabrics, dry goods, liquors, groceries, animal products, etc., in San Francisco, that pay \$27,012,881 for raw material, have \$31,333,781 invested capital, employ 9,713 white men, 2,697 women and 1,485 children, and 10,813 Chinese.

THE Indians continue to be very troublesome in the Big Horn country, Montana. Fighting between the Indians and the soldiers of Fort Pease was going on continually during January; any person who left the post was sure to be shot at, making it a difficult matter to procure provisions.

THE Keeley motor has once more been heard from—by the way of an explosion at Keeley's shop in Philadelphia.

The Mahogany G. & S. M. Co.

Some weeks ago the following proposition, signed by a large number of the creditors of the Mahogany gold and silver mining company in this camp, was forwarded for the consideration of the company in San Francisco:

SILVER CITY, I. T., Jan. 27th, 1876.
To the President and Trustees of the Mahogany gold and silver mining company, San Francisco:

The undersigned miners who have heretofore been employed by said company and left unpaid, and the merchants and business men of Owyhee county who have furnished to said company goods, provisions and material to work said mine, and are also unpaid, hereby respectfully represent that we are all great sufferers on account of the general failure of the San Francisco mining corporations to pay their obligations, and the miners particularly are actually without the means to satisfy hunger; and

WHEREAS, The Mahogany mine belonging to you is known to be sufficiently rich in gold and silver to pay all the debts of said company when honestly worked and the proceeds faithfully accounted for; and, after patiently waiting several months, we fail to discover any effort upon your part to either work the mine or pay your debts, we have

Resolved, To apply to you for permission to work said Mahogany mine upon our own account, and, after paying the necessary current expenses, to apply the surplus to the payment of the respective amounts due us; and we urgently request that you empower some person to act for you in granting to us a lease or contract embodying the principles and provisions above indicated. This is not an agreeable request for us to make of the leading corporation engaged in Owyhee, but we are driven to this alternative or the equally unpleasant ones of starvation or hunting up George M. Pinney, in Peru.

Very respectfully, yours, etc.
No response in relation to the above, says the Owyhee *Avalanche*, has been received. The Mahogany creditors, however, are invited to accept 25 cents on the dollar or take stock of the corporation in full for the amount of their claims. A proposition to that effect has been sent here by the company, having been forwarded through C. W. Moore, Esq., who arrived from San Francisco last Wednesday. The matter is to be discussed by the creditors at a meeting to be held to-morrow afternoon. The proposition to accept 25 cents on the dollar will probably meet with strong opposition, it being conceded that the offer is not sufficiently liberal to meet with favor. The parties living here, interested in these claims, are accustomed to paying their debts on the basis of 100 cents on the dollar, and, if they accept 25 cents on these and other claims, they would soon be minus the requisite means to keep up the good reputation they have hitherto enjoyed. The proposal to issue stock to the creditors in liquidation to their claims will undoubtedly be regarded with more favor than the other, although it is by no means certain of being accepted. In this matter of taking stock several things are to be considered and, among others, the question as to how many shares of stock there are in the hands of the company which they are at liberty to divide *pro rata* among the creditors. This question must be answered before a price can be set upon the stock. We understand that there is the sum of \$5,000 in the treasury of the company in San Francisco, and at the lowest estimate there is at least \$10,000 worth of ore out at the mine ready for crushing. Estimating that the hauling and milling of this ore will cost \$5,000 (it probably wouldn't cost that much) the company have an equivalent to \$10,000 cash on hand. The mine is well opened and in better condition for yielding ore than ever it was; the ledge also shows up larger and richer than at any period since it has been worked. So, taking the promising condition of the mine into consideration, it seems decidedly too bad and unjust that the Mahogany company should resort to the questionable course of endeavoring to pay its honestly contracted debts at 25 cents on the dollar.

DR. PETERMAN, the great German geographer, expresses himself satisfied that the diamond fields at Zimabwe, Africa, are identical with the Ophir of the Bible, from which King Solomon is said to have conveyed gold and ivory and precious stones for the construction of the temple. The place possesses ruins and extensive piles of buildings of unquestionably remote antiquity.

The new machinery for the joint shaft of the Amazon and Glasgow has arrived on the ground, and the grading for its reception will be finished in a day or two more, when the machinery will be immediately placed in a position for work.

The cinnabar company on Applegate, Jackson county, Oregon, are now burning a large quantity of brick to use for their furnaces preparatory to commencing operations on an extensive scale the coming summer.

AIR pipes are being put in to conduct air from the Belcher air shaft down to the 1700-foot level, and when completed will greatly aid the prosecution of work in that portion of the Crown Point mine.

A GREAT excitement has been created at Socorro County, New Mexico, by the discovery of immense deposits of copper ore.

ELEVEN men and twenty five girls are employed by the Angora robe and glove company at San Jose.

USEFUL INFORMATION.

Chewing Gum.

Under the incorrect name of hemlock or spruce gum, considerable quantities of an exudation from the hemlock or hemlock spruce are annually sold. We say incorrect name, as the article is in no sense a gum, but is properly a turpentine, consisting of a resin and a small proportion of volatile oil. It is similar in its nature to the white turpentine which exudes from the Southern pine, but having less oil, is much harder. It is also called Canada pitch. The hemlock while growing contains very little resinous juice, and the lumber is very free from it, but when the tree from any cause begins to decay, the turpentine or "gum" appears upon the surface in nodules, some of which are the size of a walnut or smaller, while others are as large as a hen's egg. It is a very common thing among young persons who live where the hemlock abounds, to get into the habit of gum chewing; the orientals use mastic for strengthening the gums and perfuming the breath, and it is possible the use of chewing gum originated in some such notion. The chewing gum of a few years ago was this turpentine of the hemlock, or spruce gum, refined, but this has latterly been superseded by paraffine, which is a white wax-like product of petroleum or coal-oil.

The resinous product yielded by the Norway spruce in its native forests is known in this country as the Burgundy pitch, and is much used for making a stimulating plaster; the hemlock pitch is also used for the same purpose, and very closely resembles the imported article in its effects. In one way and another the article finds a sale at prices which make it worth while for those who live near hemlock forests to collect the "gum," as it is always called by the country people. Early in the fall or late in the summer, after the haying is over, some of the farmers go a "gumming," as it is styled; they go to the woods, where they erect a log shanty, and proceed to collect the gum for the market. A long pole is provided, below the tip of which is fastened a circular box or receptacle, generally the leg of a boot, kept in shape by a circular piece of wood, through which the end of the pole projects; on the end of the pole is fastened a chisel. Having a satchel sling over his shoulder, the collector proceeds in search of gum-bearing trees, and when found, uses the implement. The gum detached by the chisel falls into the box beneath, and from this it is transferred from time to time, to the satchel or haversack. These receptacles are emptied into a large bag, and when this is full it is taken to the log hut. During rainy days, evenings and at odd times, the gum is freed from twigs, bits of bark and other impurities, and made ready for market. The collecting of gum is sometimes very profitable; in some cases over \$2,000 have been realized by two men in a single season, but such returns are exceptional. The season lasts until the weather becomes too cold to work in, when the camp is broken up.

DECOMPOSITION—GUARD AGAINST ITS EFFECTS.—Refuse and waste are the natural enemies to the health of mankind. The products of their decomposition pervade every household. Their offensive odors are charitable warnings to guard against. From the cellar, store-room, pantry, bed-room, sitting-room and parlor; from decaying vegetables, fruits, meats, soiled clothing, old garments, old furniture, refuse of kitchen, moldy walls, everywhere, a microscopic germ is propagating. It contains in itself the seeds of disease—all that is needed is the proper soil or condition of constitution adapted for its reception. Each germ may find its specific habitat, and hence develop into some specific malady. Typhoid, typhus, cerebro-spinal, relapsing or scarlet fever, measles, small-pox, roseola, cholera or some other form of disease may result. Cleanliness, pure air, sunlight and pure water are the antidotes. God indicates and provides these in abundance. He who neglects or rejects these deserves to suffer, as he surely will.

A CURIOUS PHENOMENON, frequently met with in the Indian ocean, the real cause of which has not yet been ascertained, is the existence off Malabar, and in certain spots along the Coromandel coast, of vast mud-banks, and of tracks of mud suspended in the sea, wherein many kinds of fish find abundance of food, immunity from much disturbance in the surrounding element, and a locality in which to breed. The exact cause of the existence of these large tracts of sea wherein mud remains in solution is still a mystery; but at any rate the ocean is so smooth that, even during the height of the southwest monsoon, vessels can run for shelter into their midst, and once there are as safe as when inside a breakwater.

TO DRILL INTO HARD STEEL.—Make your drill oval in form, instead of the usual pointed shape, and temper as hard as it will bear without breaking; then roughen the surface where you desire to drill with a little diluted muriatic acid, and, instead of oil, use turpentine or kerosene, in which a little gum camphor has been dissolved, with your drill. In operating, keep the pressure on your drill firm and steady; and if the bottom of the hole should chance to become burnished, so that the drill will not act, as sometimes happens, again roughen with diluted acid as before; then clean out the hole carefully, and proceed again.

THE MAN WHO NEVER TASTED FLESH.—There is said to be a new living, one-half mile south of Holmesdale, Penn., an old farmer by the name of Abraham Blatt, who is about 60 years of age, is healthy, robust, and as strong as a horse, who has never in his lifetime tasted the least bit of meat of any kind. He says he never tasted beef, pork, mutton or veal, eats no kind of poultry, no kind of fish, no kind of game, in fact nothing pertaining to meat. He has such an abhorrence of meat that when they kill a cow or hog on his premises, he generally leaves home and goes about other business. He is the father of a large family, all healthy children. Among them is also one boy, who, like his father, eats no meat of any kind. In reply to the questions put to the father how he could work so hard without eating any meat, he says he believes he is much healthier than if he ate meat. He uses very little butter.

TO CLEAN LOOKING-GLASSES.—Wash thoroughly a piece of soft sponge, and remove all gritty particles from it, dip it slightly into water, squeeze it out again, and then dip it in some spirits of wine; rub it over the glass, dust it with some powdered blue or whiting sifted through muslin; remove it lightly and quickly with a clean cloth, and finish with a silk handkerchief. If the glass be a large one, clean one-half at a time, otherwise the spirits of wine will dry before it can be removed. If the frames are gilt, the greatest care must be taken to prevent the spirits of wine from touching them. To clean such frames, rub them well with a little dry cotton wool; this will remove all dust and dirt without injury to the gilding. If the frames are varnished, they may be rubbed with the spirits of wine, which will take out all the spots and give the varnish a superior polish.

CEMENT FOR MARBLE AND ALABASTER.—Mix 12 parts of Portland cement, 6 parts of slacked lime, 6 parts of fine sand, and 1 part of infusorial earth, and make no into a thick paste with salicate of soda. The object to be cemented does not require to be heated. It sets in 24 hours, and the fracture cannot readily be found.

LOOSE SCREWS.—It is a common thing when a screw or staple becomes loose to draw it out, plug up with wood and re-insert. But screws and staples so secured soon come out again. It has been found that a much better way is to fill up the holes tightly with cork. Screws and irons so secured will remain perfectly tight as long as when put into new wood.

GOOD HEALTH.

Medicated ice.

The possibility of using antiseptics in medicine was recently pointed out by Edward Martin, in a letter to the *Lancet*, from which the following is taken:

"Every practitioner has at times to face the difficulties of the scarlatinal throat in young children. It may sadly want topical medication; but how is he to apply it? Young children cannot gargle, and to attempt the brush or spray often fills them with terror. In many cases neither sterility nor coaxing avails. Yet these little ones in almost every case greedily suck bits of ice. This has long been my chief resource where I could not persuade the child to submit to the sulphurous acid spray. Lately I have been trying an ice formed of a frozen solution of the acid (or some other antiseptic). Though, of course, not so tasteless as pure ice, the flavor is so much lessened by the low temperature, and probably also through the parched tongue very little appreciating any flavor whatever, that I find scarcely any complaint on that score from the little sufferers; they generally take to it very readily. The process of making it is very simple. A large test tube immersed in a mixture of pounded ice and salt is the only apparatus required, and in this the solution is easily frozen. When quite solid, a momontary dip of the tube in hot water enables one to turn out the cylinder of ice as the cook turns out her mold of jelly. I have tried the three following formulae, all of which answer, though I think I prefer the first: 1st. Sulphurous acid, one-half drachm; water, seven and a half drachms: mix and freeze. 2d. Chlorate of potash, one scruple; water, one ounce: dissolve and freeze. 3d. Solution of chlorinated soda, one-half drachm; water, one ounce: mix and freeze.

"However, the form is of secondary importance, as each practitioner can construct his own. Boracic acid, salicylic acid, or any other harmless antiseptic with not too much taste, would, doubtless, be as useful as those indicated."

DRY EARTH treatment for ulcers has been found very successful. Large, sloughy ulcers, after being washed, were covered with a thick layer of earth, over which wet paper was placed as a support, the whole being neatly bandaged. In a few days the ulcers began to clear, and when the surfaces looked healthy and granulating, a dressing made as follows was used: A piece of muslin the size of the ulcer was immersed in carbolic oil (in the proportion of one part acid to ten parts cocoon oil); with this the sore was covered, and over that dry earth was placed, and then moistened earth and a bandage. In a short time the healing process manifested itself satisfactorily, while all odor was entirely removed.

Rheumatic Recipes.

The *Journal of Health* has patiently collected and published 100 recipes for the cure of rheumatism, and spreads them before its readers in the following manner:

Rochelle salts. Gualiacum. Rub with chloroform liniment. Sleep with your head toward the north. Nux vomica. Wear a chest protector. Nitrate of potash. Nitrate of sodium. Fowler's solution of arsenic. Sleep with a big dog and give it to him. Kill a big dog and, after taking out his intestines, put your feet where they came from. Magnetism. Galvanism. Bromide of ammonium. Iodide of ammonium. Mustard plasters. Spanish fly plasters. Bromide of potassium. Iodide of potassium. Lemon juice. Sage tea. Wear sulphur in your shoes. Hard rubbing. Oleate of mercury. Common soda. Capsicum. "Ridway's Ready Relief." Wear silk. Wear flannel. Wear buckskin. Gird and hemlock. Reynolds' specific. Make a necklace of the knots produced by the sting of an insect on "Golden Rod," and wear it next the skin. Citrate of lithia. Exercise and keep it off. Keep as quiet as possible. Colehiem. Morphine. Water cure. Angel's rheumatic gum. Pray fervently. Soft soap, bandaged with flannel. Do not eat meat. Do not eat eggs or potatoes. Eat anything you please. Opium. Do not smoke at all. Smoke all you like. Take camphor. Drink nothing but beer. Do not drink anything but whisky. Do not drink anything at all. Do not leave the house. Take a ride out whenever you can. Carry a piece of alum in your pocket. Take Turkish baths. The Turkish bath is one of the worst things for rheumatism. De Soto spring water. Acetate of potash. Burdock seed. Bathe in hot water with perlash in it. Bathe in cold water frequently. Do not bathe at all until you are nearly well. Cut up tea. Wrap fresh lamb's entrails around your neck. Drink brandy. Brandy is very bad for rheumatism. Sleep next to flannel. Go to Arkansas hot springs. Go to Doolittle springs—to Saratoga, to Florida, to Bermuda, to the Sandwich islands, to California, to the south of France, to Mexico, to the Azores, to South America. Wear a horse chestnut in your left hand breeches pocket. Wear a potato in the other. Take "Constitution water." Take carbolic acid. Wrap joints with cotton, and cover with oiled silk. Glen Flora water. Get out on the prairies. High land is best for rheumatism. Balm of life. Magnetic aloe. Rub with kerosene. Mustang liniment. Read Job. Put on hot poultices. Apply hop mashes. Do not swear. Put mustard plasters over the heart. Drink Friedrichs' bitter water. Sciditiz powders. Take a quart of alcohol with a dozen lemons in it. Take spirits of turpentine. Rub with spirits of turpentine. Slippery elm poultice. Electric oil.

Any disease that won't succumb to one or all of the above remedies must be hard to cure.

DISEASE AND ITS CAUSE.—On inquiring recently about the health of a lady to whom I had just been introduced, she said her health was not good; that she was subject to frequent attacks of chills and fever. I asked her if she lived near a swamp or a stream of water. "Why, I live," said she, "on the bank of a large millpond that is covered with green slime!" No. 2. A man and his wife were both taken sick the same night, the one of spinal meningitis and the other of diphtheria. Having occasion to enter the house a few days later, I was almost knocked down by a stench which I had never before encountered. It was fairly penetrating, like the ammonia that rises from fermenting stable manure. Strange to say, both of these persons have recovered. No. 3. In the same village is a slaughter house, to the rear of which is a pen containing some half a dozen filthy-looking hogs wallowing in filth three or four feet in depth, consisting of beef skulls, bones, entrails, blood and manure, and all this in less than two rods from the residence of the owner, whose wife and only daughter now lie sick of typhoid fever. Regarding the cause of these sicknesses, I do not think there should be much doubt, or that the sick persons deserve some punishment for their disregard of the laws of health.—*N. Y. Tribune.*

DEATH FROM THE STING OF A BEE.—On the 4th of last September a young girl living at the hamlet of Crevecoeur was stung by a bee on the left cheek and died a few minutes afterward. She had manifested symptoms of nervous disorder, supposed to be hysterical, previously. A year and a half before she had been stung by a bee and had remained insensible for more than four hours afterward.—*Les Mondes.*

SUFFOCATING INFANTS.—At an inquest held in London, the other day, on the body of an infant that had been suffocated in bed, the deputy coroner said the frequency of those cases was alarming. Upward of 300 children were suffocated in bed annually in the central district of Middlesex alone. Seven-tenths of these suffocations occurred on Sunday mornings.

CHOKED BY A TOWEL.—A very singular accident happened to a boy in Fulton county, Ill., a few days ago. While wiping himself with a ragged towel he inserted his head through a hole in the cloth, and while in this situation he was suddenly taken with a fit and fell, and the towel closing around his throat, he was strangled to death before he was discovered.

DOMESTIC ECONOMY.

House Mats.

Editors Press:—My "better half" has just notified me that I must inform the Press readers and "Sister Grangers," how to utilize old bay ropes by making them up into door mats, buggy mats, etc. Take a coarse potato sack, stretch it upon a frame a size larger than the sack; then take a coarse needle and twine, sewing the sack to the frame by a stitch which tailors would call "over and over." Prepare a needle for working in the rope from an old table fork, filing it into shape like a crochet needle, only stout enough in the cavity, or hook, to hold the rope, thus:

The work is performed the same as in making a rag mat. The rope is some half inch free on top, and cut with sharp scissors after being hooked in. This mat is not a fancy piece of work, but will be found serviceable and durable, costing nothing but labor, which becomes almost a recreation.

There are generally waste ropes in abundance around rural homesteads, which are considered useless except to tie up old barns and balter ropes, which would place a useful mat at every door of the house, and supply the buggy besides. This work may be performed on rainy days, or during long winter evenings, by old or young, man or maiden.

The plethoric wealthy need not look up for old broken tinied forks, or waste bay ropes. 'Tis only for the industrious poor, securing a necessary comfort for a clean house at small expense. How many days are spent in fine fancy work by dainty fingers, while muddied boots are making muddy floors, all of which might be avoided by a potato sack bay rope mat. JOHN TAYLOR.

Chinese Camp, Feb. 11th, 1876.

Nutritive Food.

In 1868 Liebig invented a new soup for children, now universally known as "Liebig's food for infants." Wheat flour or powdered malt is transformed into dextrose or dinstase, at the proper temperature, while milk and some potassium carbonate are added. The principle is to produce a food as much as possible similar in composition and action to woman's milk. This exquisite mode of preparing food for infants (which I have employed for years with the most perfect success) would be a much more suitable lesson for schools of cookery than the preparation of offal into the semblance of savor. The problem of feeding the young and the poor physiologically is not easy, but it is simple if considered from the scientific point of view. The bulk of the food of the lower classes must always be bread; it is perfectly idle to believe that this can be altered. Peas, beans, and other like leguminous plants, however rich in albumen, can never compete with bread; first, because they require steeping in water and boiling for hours; next, they become hard so easily, and then are indigestible, while at all times they are not so easy to be digested as bread. But bread is not so good a food as meat; here chemistry comes in, and, as Liebig says, shows that bread soaked in broth made from extract of meat is as good food as the best meat diet. In this, as a practical proposition, I fully agree.

A man who is physiologically fed, though without regard to much taste in the food, may be in the best possible physical condition and vigorous. He has the privilege of the animal, which is contented with and thrives upon things which have no prominent taste and require no spice. The fowl can taste nothing of the whole corn which it eats, yet how eagerly does it eat of it! It knows its nutritive value as a matter of inner consciousness. Thus, when our population will use more meat extract, and perhaps a little less tea and more of Liebig's food for their strength, health and vitality, and will find for themselves that the greatest good of life is health, and that no artifices of small cookery will be worth having, which are, as they must be, unable to maintain the body in vigor.—*Cantor Lecture.*

MINCEMEAT FRITTERS.—With half a pound mince meat mix two ounces fine bread crumbs, or a tablespoonful flour, two eggs well beaten and the strained juice of half a small lemon. Mix these well and drop the fritters with a dessert spoon into plenty of pure lard; fry from seven to eight minutes, drain them in a napkin and send them very hot to the table. They should be quite small.

PULLEN BREAD.—Pull the soft portion of a new loaf into pieces; let them be of equal size, say about two or three inches each way. Dry the pieces in a slow oven or before the fire till they become a nice light brown color, and when they are quite crisp they will be ready for use. They are very nice with coffee.

HOW TO MAKE THE TEA GO FURTHER.—A method has been discovered for making more than the usual quantity of tea from any given quantity of the leaf. The whole secret consists in steaming the leaf before steeping. By this process, it is said, 14 pints of good quality may be brewed from one ounce of tea.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Abbott Concrete Pavement, 161. Engineering Abroad; Idaho Mines; Mining Matters in Congress, 163. Mining Debris; Portable Show Case; The Frisco Rein Holder, 169. Patents and Inventions; Notices of Recent Patents; Gems and Precious Stones; Academy of Sciences, 172.

ILLUSTRATIONS.—The Abbott Concrete Pavement, 161. Basmitt's Portable Show Case; A New Rein Holder, 169.

CORRESPONDENCE.—Botanical Excursions, 162.

MECHANICAL PROGRESS.—A New Photographic Printing Process; Covering for Boilers and Steam Pipes; Utilizing Coal Dust; Cutting Steel with Soft Metal Discs; New Explosives; Lock Weld Arvils; The Number of Bessemer Steel Works in the World; The Future of Petroleum, 163.

SCIENTIFIC PROGRESS.—How the Sky Looks to "The Man in the Moon"; How Plants Absorb Nitrogen; A Thought on Astronomy; Scientific Progress; Bacteria Found in the Perspiration of Man; Interesting Mineral Specimens; Important to Botanists; Photography; Very Minute Animals; A New Mineral; The Action of Saliva, 163.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 164.

MINING SUMMARY from various counties in California, Nevada, Montana and Idaho, 165-172.

USEFUL INFORMATION.—Chewing Gum; Decomposition—Guard Against Its Effects; To Drill into Hard Steel; The Man who Never Tasted Flesh; To Clean Looking-Glasses; Cement for Marble and Alabaster; Loose Screws, 167.

GOOD HEALTH.—Medicated Ice; Rheumatic Recipes; Disease and Its Cause; Death from the Sting of a Bee; Suffocating Infants; Choked by a Towel, 167.

DOMESTIC ECONOMY.—House Mats; Nutritive Food; Mince-meat Fritters; Pulled Bread; How to Make the Tea go Further, 167.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 173 and other pages.

MISCELLANEOUS ARTICLES.—The Wallace Ferguson Mine; California Cnr Wheels; N. P. R. R.; Egyptian Irrigating Appliances, 162. Scientific and Practical Ballooning; How They Do It Here; Hidden Dangers; Celluloid; Are They to Have a True Republic in France? Eating Quails; Business Outlook; The Newspaper Business; The British Coal Industry; Brooms; Mammoth Bunches of Grapes; The Mahogany G. & S. M. Co., 168. The Eames Quicksilver Furnace; Mining Decision; Butte County Mines, 170. The Lone Valley Coal Beds; Mining in Montana, 174.

NEW ADVERTISEMENTS.

Cameron's Steam Pump, Neylan & Young, S. F.; Hoadley Portable Steam Engines, Treadwell & Co., S. F.; Klamath Quartz Mining Co.—Assessment; Golden Sun Mining Co.—Assessment.

QUICK WORK.—The Consolidated Virginia mining company on Tuesday shipped 107 bars of bullion, weighing over six tons and valued at \$378,232.55. This is the largest single shipment ever made by any company on the Comstock lode. The Belcher company once made a shipment of \$335,000. The work of melting and assaying the large amount of bullion mentioned above was commenced on Monday morning and finished on Tuesday morning by 11 o'clock, there also being made during the time 140 ore assays. This is undoubtedly the biggest work ever done in the way of melting and assaying silver bullion.

THERE is great excitement in Utah over the discovery of rich mines south of Pioche, near the Arizona line. One of the discoverers arrived at Ogden with a few tons of the ore, which he sold for \$12,000, and stated that there was a great quantity of it, and he created such an excitement that several are preparing to leave Ogden for the scene of operations.

A MINING company in Spruce Mount hired all the labor and bought all they could on credit, and then sold out, failing to settle their bills.

Engineering Abroad.

Prof. George Davidson, of the United States Coast Survey, President of the California Academy of Sciences, returned this week from a tour of observation around the world, having been absent some 18 months. He left here as one of the observers of the transit of Venus for the United States Government, having in charge a party of observers in Japan. His travels extended to Japan, India, Egypt, and all through Europe, his principal object being the gathering of information with regard to the different plans and the latest improvements in civil engineering in general, and especially in the departments of harbor and river engineering and irrigation. Prof. Davidson is one of the Commissioners of Irrigation appointed by the Government, and is thoroughly conversant with the needs of California in the matter.

The Professor gave an outline of the subjects which he examined abroad, and stated he would have the pleasure—beginning, perhaps, at the next meeting—to present to the Academy the results of his inquiries into harbor and river improvements, irrigation and the use of instruments of precision. He trusted that the matter would prove interesting and valuable to civil engineers.

Irrigation.

Prof. Davidson stated that in India he had found irrigation carried on in an excellent manner, and on a scale of magnitude of which Americans can form no conception from the descriptions received. The system was a thousand of years old, but the ability of the English engineers had corrected its defects. Their improved methods, the Professor thought, might be used with peculiar advantage in California. He had taken notes of the Egyptian water works, and the disadvantages of the inundation of the Nile, upon which the agriculture of Egypt depends. The country consists of the valley of the Nile, with only seven and a half million acres of arable land, the whole of which is less than the Sacramento and San Joaquin valleys, measuring from where the foothills are three hundred feet. The Egyptians have one crop a year, and that is hazardous, depending upon the rise of the river. Outside the valley are the deserts. The Khedive, as an able ruler, is endeavoring, through his English engineers, to improve the ancient system.

In Italy, on the other hand, the system of irrigation has been so perfected that Piedmont and Lombardy are gardens, with two grain crops and three root crops a year. Their system of reclamation along the lower reaches of the Po is the same as that of Holland, but the defects of their labor system are such that little is to be learned from them, except in the way of details and to profit by their mistakes.

Artificial Harbors and Railroad.

He examined all the artificial harbors in Europe and was glad to note that the engineers were able and willing to describe every detail of construction and give every opportunity for examination. They were also willing to point out the errors they had made, that others might profit by them. He has numerous drawings and details of these works to bring before the Academy.

In railroad engineering he had found nothing in all Europe that compared in boldness of conception and rapidity of execution with our own Central Pacific and Union Pacific roads. The nearest approach to it was in India, in the case of the Bombay railroad, where many weighty obstacles had been overcome. The highest elevation above the sea of that railroad was, however, only 1,500 or 1,800 feet. In the details of some engineering projects he stated that some of the foreigners excel, but that in great ideas and projects we are far ahead. Their embankments in Europe are smoother and their tunnels better, but their efforts seem to have been limited as compared with the stupendous ideas of the Americans.

Europe a Camp.

The Professor, in conclusion of his remarks, said that he returned more Californianized, if possible, than ever. Europe was simply a vast military camp. Every industry is subordinated to the domination of the war power. It reverses the law of the survival of the fittest and depresses everything by the principle of conscripting the flower of the people. He thought Americans should feel peculiarly thankful for that freedom which allows such individual development. And although we are open to the criticism of proneness to self-praise, we may do our boasting with conscious pride. The Professor said he had not seen in Europe so good an attendance of members of scientific societies as was present last night, nor so much interest taken as marked the California Academy, and concluded with heartiest good wishes to all the members.

THE total yield of the Consolidated Virginia mine for the month of February is \$2,800,000—a yield unprecedented in the history of mining, but one which will doubtless be surpassed next month.

TWO new postal cars for the Central Pacific railroad, with all the modern improvements and conveniences, have just been turned out of the railroad shops at Sacramento.

Idaho Mines.

A correspondent who writes us from Placerville, Idaho Territory, says the miners are very jubilant at the prospects of having a good winter season in the Territory. In many places the snow is six feet deep on a level. The Gold Hill mill is running steadily with 25 stamps, and the rock is very rich in gold. They have been sinking this winter and tapped the ledge at a depth of 100 feet, with a rich body of ore in sight. John Eisler is running a tunnel that will tap the extension of the Gold Hill mine at a depth of 200 feet, and the work is progressing very satisfactorily. He expects, in a few months, to be crushing quartz. He has a fine 10-stamp mill neatly fitted up and convenient to the mine, so that he can start up the mill at any time, as everything is in readiness for working. Our correspondent says he is very well pleased with the MINING AND SCIENTIFIC PRESS, and the miners all say that such a paper deserves a liberal patronage.

We hope other of our subscribers in Idaho and elsewhere will follow the example of the one above quoted, and write us whatever items of interest they find leisure to communicate. In Idaho we have many readers, and desire to do the pleasant duty of fairly representing its rich resources. The Idaho mines which are known in this city have been under a serious cloud for some time, but this is without doubt caused more by mismanagement of officials than by any demerits of the mining property itself. Some of the Idaho mines called on the Stock Boards have depreciated in price so as to be almost worthless—an effect produced by the repeated levying of assessments. It has become so bad that people fight shy of Idaho mines altogether, and do not want any stock in them at any price, so that the mines of the Territory are in bad repute.

This is the case, although it is a well known and acknowledged fact that these circumstances are entirely owing to the fact that those who have controlled and managed these stocks for the past few years, and have so manipulated them as to disgust a long suffering community, have only run the mines for stock jobbing purposes. They seem to have run things into the ground with a vengeance. All this has been so bad that a change is about to come, and it is probable that before long the mines will be worked on their merits. The miners have been defrauded of their just earnings, and they seem not to have been able to come to any fair understanding with the owners. The residents of Owyhee have every confidence in their mines, and judging from reports in the local press, which labor hard to keep the merits of the mines before the world, the property is valuable and would pay well if judiciously managed. Our mining summary gives the details of working of the prominent mines at present. We sincerely hope for brighter times for the Idaho mining interests.

A Miner's Suggestion to the Centennial Commissioners.

EDITORS PRESS:—Through your valuable paper I propose to make a suggestion to the Centennial commissioners, whereby the yield of all the mines of this State for the month of May will be placed on exhibition at Philadelphia, in conjunction with that 150 tons of gold and silver bricks which the Consolidated Virginia and California mines are going to furnish.

I understand that the Government purchases the bullion from those mines. Why cannot the commissioners make arrangements with the Government for the purchase of the bullion from all the mines of this State? Let it be advertised in time to be generally understood that such an arrangement can and will be made. Then, let the commissioners solicit all mining companies to make it a point to collect and forward their bullion for said month to some place—say the mint—where its value may be ascertained and paid; small quantities of gold might be collected by the gold dust buyers through the country, and forwarded in the same way. Each company that so chose could have its bars kept separate, and stamped with its name; bars forwarded by dealers could be stamped "miscellaneous."

This whole matter could be arranged with but very little trouble and expense, and would be a great feature of the exhibition, and would do more towards directing the attention of the world to our mines than the enormous exhibits that a few companies will be able to make.

I am a miner, and will be producing bullion at the time here spoken of, and will gladly enter into some arrangement of this kind, and believe that mining men will at once see the propriety of contributing to something of this kind if the way is once marked out and made easy.

With these remarks I submit the proposition to the commissioners, or to any other parties who may deem the proposition worthy of consideration, hoping that such action may be taken in the matter as will make it a successful feature in our national Centennial exhibition.

N. CADWALLADER.

Sweetland, Nevada Co., Cal.

THE Silver State says it is reported that Flood & O'Brien are negotiating for the purchase of the White and Shiloh mine at Galena, Lander county.

Mining Matters in Congress.

Nothing at all affecting the mining interests of the country has occurred during the present session of Congress, except the bill introduced by Delegate Patterson, of Colorado, last month and mentioned by us at the time. Since then the Committee on Mines and Mining to whom it was referred, have reported a substitute for the Patterson bill, which we give below. The bill is to amend Section 234 of the Revised Statutes concerning mineral lands. This section is probably the most important in the mining laws of the United States, since it specifies the method of location and the expenditures required to hold claims, after they are located. It also specifies the legal method of getting rid of non-paying partners in mining claims—a matter of great importance to miners. In order that our readers may understand what the amendments are, we first give Section 2324 of the Revised Statutes:

SECTION 2324. The miners of each mining district may make regulations not in conflict with the laws of the United States, or with the laws of the State or Territory in which the district is situated, governing the location, manner of recording, amount of work necessary to hold possession of a mining claim, subject to the following requirements: The location must be distinctly marked on the ground so that its boundaries can be readily traced. All records of mining claims hereafter made shall contain the name or names of the location, the date of the location, and such description of the claim or claims, located by reference to some natural object or permanent monument as will identify the claim. On each claim located after the 10th day of May, 1872, and until a patent has been issued therefor, not less than one hundred dollars' worth of labor shall be performed or improvements made during each year. On all claims located prior to the 10th day of May, 1872, ten dollars' worth of labor shall be performed or improvements made by the 10th day of June, 1874, and each year thereafter, for one hundred feet in length along the vein until a patent has been issued therefor; but where such claims are held in common, such expenditure may be made upon any one claim, and upon a failure to comply with these conditions, the claim or mine upon which such failure occurred shall be open to relocation in the same manner as if no location of the same had ever been made, provided that the original locators, their heirs, assigns or legal representatives, have not resumed work upon the claim after failure, and before such location. Upon the failure of any one of several co-owners to contribute his proportion of the expenditures required hereby, the co-owners who have performed the labor or made the improvements may, at the expiration of the year, give such delinquent co-owner personal notice in writing or notice by publication in the newspaper published nearest the claim, for at least once a week for ninety days, and if at the expiration of ninety days after such notice in writing or by publication, such delinquent should fail or refuse to contribute his proportion of the expenditure required by this section, his interest in the claim shall become the property of his co-owners who have made the required expenditures.

The above is the original section, which is now the law. Below we give the substitute for Patterson's bill, referred to above, reported to Congress by the Committee on Mines and Mining.

A bill to amend Section 2324 of the Revised Statutes, concerning mineral lands.

Be it enacted, etc., that Section 2324 of the Revised Statutes be amended as follows: Where the words "until a patent has been issued therefor" first occur in the said section, the same shall be stricken therefrom, and there shall be inserted in their stead the following: "Until an application for a patent therefor and final proofs and payment for the claim have been made, as required by the terms of this chapter." And where the words "until a patent has been issued therefor" occur the second time in said section, the same shall be stricken therefrom, and there shall be inserted in their stead the following: "Until an application for a patent therefor, and final proofs and payment for the claim have been made, as required by the terms of this chapter: *Provided*, That where an application for a patent has been filed in the manner prescribed by this chapter, and an adverse claim asserted against the same and suit commenced thereon, the annual expenditure for labor or improvements hereinbefore prescribed shall not be required until the right and title to such claim shall have been finally determined by a court of competent jurisdiction."

It will be seen that the words "until a patent has been issued therefor," limit in the first of the two places above indicated the time up to which an annual expenditure of \$100 is required by the existing law on each claim located after the 10th of May, 1872. Where they occur the second time they limit the duration of the requirement for an expenditure of \$10 worth of labor or improvements every year for each 100 feet of length along the vein of every claim located prior to May 10th, 1872. The sentence after the word "Provided" explains itself.

At the Hale & Norcross mine they spent the whole of last week in pumping the water flowing from the Savage mine, without producing any favorable result whatever.

Mining Debris.

In the State Legislature this week the Assembly Committee on Agriculture presented the following report on the evils resulting from hydraulic mining. They recommend the passage of a substitute bill for that referred to them (which we recently published), and the adoption of a memorial for a Congressional investigation. We shall give next week the report of the Committee on Mines, to whom the same subject was referred, and who will give a totally different showing:

Your Committee, to whom was referred Assembly bill, "An Act to establish a Commission relative to Hydraulic Mining and the damages resulting therefrom," having given the subject such consideration as the limited time at the disposal of the Committee of the House will admit of, we are satisfied that any such consideration is, and of necessity must be but partial, and that the only manner in which it can be treated calculated to do justice to the great interests involved is by adopting the system proposed in the bill, to wit: The appointment of a commission capable of grasping the subject, and with time to treat it fairly, and without doing injustice to either of the interests involved. We find that

In Years past Mining was the Prominent Industry. Almost the only one of our State—that the gold hidden in our mountains and along our streams was the only inducement to us who came here in early years, that it was thus enabled and allowed to overshadow all other industries, to take within its grasp the right appertaining to tillers of the soil, until it became a maxim that no farmer or horticulturist had any rights which the miner was bound to respect. This feeling largely influences our thoughts even to the present time, and permits the miner to work down the hills and the mountain side, depositing the tailings, the sand, gravel and boulders on the valley lands below him. It is a principle of law "that no man or body of men have a right to follow any calling or industry which inflicts damage or wrong on other men." Yet this has been done for years, and notwithstanding the immunity from damages inflicted on others we find the production of gold steadily on the decline.

The Damage Specified.

Your Committee find from evidence adduced that the valleys of the American, Bear, Feather and Yuba rivers commenced to be injured by the detritus from the hydraulic mines about the year 1862. That the owners of lands in the river bottoms did for a series of years and at very great expense hold the increasing debris in check, by levees, until the spaces between these rivers became filled up. The water would then break through the levees, carrying the sand, gravel and cobble-stones upon the lands, destroying their fertility, rendering lands once the richest in the State unproductive and valueless. This system has continued until nearly all the valuable bottom lands of these rivers have been utterly ruined. Where once stood fine mansions and pleasant houses, rich orchards and fields, smiling with golden grain, is now to be seen but sterrenness and desolation—a sandy waste. We find that the lands so destroyed were worth many millions of dollars; that their ability to return a revenue to the State has ceased. But this is not all. The destruction is but commencing, for hydraulic mining is but in its infancy and the science and appliance brought to bear enable the miners to literally move the mountains into the valleys, and so rapidly that only the costly levees built on the west bank of the Feather river prevents the large and fertile territory in Sutter county from being destroyed, but the deposits from the mines is increasing at so rapid a rate that the levee system is becoming almost unavailing, rendering it impossible to preserve for agriculture a territory whose annual production exceeds the gold product of all the hydraulic mines of the State.

Inevitable Result of Continuing the System—The City of Marysville.

This territory in Sutter county will be irrecoverably lost to its owners and to the State, impairing its revenues, lessening its productivity and deterring immigration. Nor is it merely by destroying our valley lands that the present system of mining is destructive. The beautiful city of Marysville, 15 years the third city of the State in population and wealth, is now from this cause alone reduced in wealth and population to the rank of ninth or tenth. Having the best natural situation of any of our interior cities—at the confluence of the navigable streams, sitting on a plateau rising 30 feet above the level of the streams flowing at her feet, and surrounded by extensive and highly fertile territory, she once bid fair to become the chief inland city of the State. But the mountains began moving down upon her, filling the beds of her crystal streams with mud, until now the rivers above which she proudly sat look down upon her streets, menacing the lives as well as the property of her citizens. A year ago the city was inundated, and \$1,000,000 worth of property destroyed. At the cost of thousands of dollars a new levee has been built, but the turbid streams already threaten its existence.

The report continues: "We find that the present system of mining destroys by a double process; first, by covering the alluvial lands of the valley with the debris from the mountains, and secondly, by stripping the hills and moun-

tains of their trees and vegetation, thus removing the soil and leaving but the bare rock. This prevents all productivity in the future. The effect this may have upon our climate for evil is yet to be determined, but can scarcely be estimated from any data at hand. During this period, while the mining interest has steadily declined—while the annual gold product has fallen from more than \$60,000,000 to about \$17,000,000, the agricultural interest has steadily and rapidly increased until now its products exceed in value the gold product of the most prosperous year.

Value of the Property Destroyed.

The report, after expatiating at length upon the place of agriculture in the State's economy, proceeds: "Evidence has been adduced, and no attempt has been made to controvert it, that in the valley of the Yuba there has already been destroyed and abandoned 29 sections of land, worth more than two millions of dollars; on the Bear river, 36 sections, worth at the lowest estimate \$1,500,000; on the Sacramento, 16 sections, valued at \$750,000; on the Feather river, eight sections, worth \$500,000; and on the American river, 10 sections, worth \$600,000 and on other smaller streams some 22 sections, worth \$1,000,000, making a total in lands above \$6,350,000. The improvements on these lands—houses, barns, fences and orchards, all that go to make homes for a thrifty and industrious people, were worth fully as much more or a total of \$12,700,000. The lands thus already

HASENRITTER'S PORTABLE SHOW CASE.

rendered unproductive amount to 77,450 acres. Estimating the annual productive value of these lands at \$30 per acre, the amount of \$2,323,200 is annually lost.

Another Evil Impending.

It is not only the lands bordering on smaller streams that are threatened. Another, and to many minds a more serious evil, is impending—the filling up of our navigable streams, unfitting them for purposes of transportation, depriving us of the great natural highways for cheap freights; the gradual filling up of our magnificent bays, with the inevitable shoaling of the entrance to the harbor and bay of San Francisco—the gateway for all products, our chief means of communicating with the world. We find that some of our rivers already, at the point of debouching from the mountains, have been raised above their nominal level from 70

feet to the waters leave the foothills, thus allowing nothing but the lighter sediment to be carried to the valleys. The committee is not prepared to advocate any plan, believing that sufficient data and statistics have not been collected upon which can be predicated legislation. In conclusion, the committee recommends the passage of the bill in order that the necessary information be obtained.

Portable Show Case.

There exists at the present time, among those who purpose exhibiting goods at the coming Centennial, an increasing demand for simple, portable devices adapted to holding articles while displaying the same to good advantage. We illustrate on this page a show case which is designed to be boxed up with the goods before forwarding, so exhibitors can be sure that their display will be well secured.

The advantages of the invention, which is represented in perspective in Fig. 1, are that it is composed of a number of easily detachable pieces, which allow of its being packed into small compass, and which, when set up, form a strong case, the joints of which cannot work loose through the effects of dampness.

As shown in the sectional views, Figs. 2 and 3, the posts, A, are attached to the bottom of

the case by screws, and in their sides grooves are formed to receive the ends of the panes of glass. On the under side of the top and on the upper side of the bottom are fastened small strips, which also have grooves to receive the edges of the glass and besides serve to brace the posts in position. The top is also attached to the post by screws, and by removing it the glass may be easily disengaged, the doors which are hinged to the rear part of the bottom taken off, and the whole case thus separated into several portions.

The device thus constructed, it is claimed, may be more cheaply and easily made than those not constructed to take apart. The case may be made of any shape, upright, octagon or round. The posts and strips can be produced in long pieces, like molding, and polished and finished before being cut. The bot-

A NEW REIN HOLDER.

tom to 100 feet, while 20 or 30 miles lower down in the valleys they have been raised but from 20 to 30 feet. This has given a greater fall to water and greater rapidity. The consequence is that heavier material is borne further down, and shortly we shall see the advancing columns of coarse gravel, rock and heavy detritus pushing into the bay. The quantity is so great that it is estimated by one of our most accomplished engineers (Mr. Arnold) to be sufficient to cover in one year one square mile to the depth of 41 feet three inches, or to fill Suisun bay to the line of low water in a period of 15½ years, and San Pablo bay to the same line in 30½ years.

Mining and Agriculture Compared.

The report continues: The lands the mines destroy would be valuable for ages to come. The people engaged in agriculture instead of destroying are steadily enhancing the value of their lands. They build permanent houses and add continuously to the productivity, the wealth and revenues of the State. Wise statesmanship demands that the permanent industry shall not be injured by the transient industry, and that the tiller of the soil shall be protected and fostered.

The Remedy Suggested.

In the opinion of many whose views are entitled to great weight, it is quite possible to regulate mining so that it will not injure agriculture. This can be accomplished by precipitating the heavier portions of the tailings be-

The 'Frisco Rein Holder.

When a teamster wants to stop he pulls the reins and his horses are drawn back so that they cannot stretch the traces. Some exceptional horses can draw a light wagon by the bit, but the strain is so great that they will not go either fast or far, and ordinarily will stop so soon as they find that the draft is thrown on the mouth, and not on the shoulders, where it should be. These facts are the basis of the rein holder, a device to keep the reins in the position in which the driver places them when he stops. Having thus fastened the reins, he can with safety leave his team anywhere far from a hitching post.

Several kinds of rein holders have been made, but that called the "'Frisco rein holder," invented by Jefferson Kindelohger and patented March 10th, 1874, is the smallest, lightest, simplest in construction, the most convenient for use and for fastening to different vehicles, and the cheapest. It is made of malleable iron or brass, weighs from two to four ounces and costs from 50 cents to \$5—the last the price for plated work. There are different patterns, suited to various vehicles and positions, not for catching leather straps only, but also clothes lines, ropes, cables, shoe strings, etc.

The illustration by our engraver shows the rein holder in three positions. Fig. 1 represents it in perspective, as it may be fastened by screws to the front of a wagon bed, or with the help of clamps on the front of the iron frame of a heavy dash-board. Fig. 2 represents a cross section of the same rein holder empty. Fig. 3 represents the same gripping the reins. A the hook, B the tongue, and E the base, are cast in one piece. C the crescent—the convex side of which is turned towards the horses—swings on the pintle D, and whenever the reins are pulled, presses them against the tongue B and holds them fast; the harder the pull, the tighter the grip. Every vehicle, header, harrow, plow, cultivator, and other article drawn by horses should have a rein holder, even if only to keep the lines out of the dirt. The driver can slip the lines in or out without effort. The patent, obtained by Dewey & Co., patent agents, is the property of J. S. Hittell, 529 California street, S. F.

NEW QUARTZ MILL.—We have examined this week drawings of a new quartz mill now being made in Sacramento by Cowles & Cooper, one of them being in operation in Tuolumne county. It is built on the principle of the Chilean mill, but with many improvements. Only one crushing wheel is used, and on the other end of the shaft, where the other wheel would be in a Chilean mill, is a unique device for stirring up the quartz and assisting amalgamation of the gold or silver. The power is applied to the rim of the wheel, which is neither suspended or driven from its center. It is geared in an ingenious way, so as to take little power to run the 16,000 pound wheel. The wheel, from its peculiar motion, grinds as well as crushes the ore. The mill now in use in Tuolumne county is said to crush about 35 tons a day through a No. 50 screen. The shoes of the wheel and bed plates are made of hard cast steel and will wear a long time. The device is quite simple, and the manufacturers inform us that they have a number of orders to fill as soon as the roads in the interior are in fit condition for hauling heavy freight. We shall give a detailed description and illustration of this new quartz crushing appliance in our next issue.

THE STEAMBOAT SPRINGS COUNTRY.—The Steamboat springs country is a singular place. Not only are they finding cinnabar there in large quantities, but they have also discovered, among other curious things, a paint mine, where the paint is said to be in streaks of various colors, and feels like white lead ground in oil. In places where sulphur digging is going on, the ground is so hot at a depth of three or four feet that the sulphur found can scarcely be held in the hand. The cinnabar excitement runs high, and claims are being staked off in every direction. Numerous sulphur claims are also being located. In some places solid masses of sulphur are reached upon the removal of from three to five feet of surface soil.

THE BOILER INSPECTOR BILL.—The Assembly San Francisco delegation report a substitute for Pullen's bill to appoint an Inspector of Stationary Boilers in San Francisco, which we published last week. The substitute leaves the appointment with the Supervisors. The Inspector is to give bonds in \$10,000. He is given power to license engineers, and to extract a fee of \$2 for each license. The fee for inspection is put at \$3 for each boiler. He is to provide all requisite machinery for carrying on the work of inspection, and the first Monday in May next is fixed for the time when the act shall take effect.

THE recent snows are interfering quite seriously with the transportation of ore to some of the mills outside of Virginia City, such as can only be reached by wagons. There is no trouble, however, in regard to keeping a full supply at all the mills on the railroad and its branches, and at all these mills there are now considerable accumulations of ore.

The Eames Quicksilver Furnace.

A recent number of the *Russian River Flag*, in recording the proceedings of the annual meeting of the Mount Jackson mining company says: The remodeled furnace of this mine is working as well as any, where the fire passes through uncrushed rock, but like all others of the class, fails to work up the dirt satisfactorily. Therefore arrangements have been made with the patentee to have three Eames furnaces erected at once, which will not only work the dirt, but also the rock. Mr. Eames' progress in bringing his furnace to perfection has been observed by the Mount Jackson company with the intention if successful to have him at once construct several of them at their mine. Mr. Eames' success justifies the above action, and a greatly increased product from this mine may be expected.

In another part of the same issue the *Flag* says: The Eames furnace is a success—and the problem how to make our quicksilver mines pay is solved. By reference to an article in another column headed "The Mount Jackson mine," and also to a statement given below, it will be seen that this furnace is not only endorsed, but also proven a success. A revolution is evidently at hand in our quicksilver mining interests. The many mines in the respective districts of which Healdsburg is the central point, which although known to be rich in cinnabar or native quicksilver have been shut down, and some abandoned, on account of failure to extract the metal, will now be revived and rendered active again, by the use of the new furnace. By its use, such rock or dirt as has heretofore been regarded as waste can henceforth be worked at a profit. Its cost is much less than any yet constructed in our mines; it is self-feeding and self-discharging; roasts either dirt or rock and the dirt does not require to be made into adobe; it is economical, as an eight-ton furnace burns but half a cord of wood per day of 24 hours, and it extracts mercury to the full assay of the rock. The scientific principle is that the regulation of air in the furnace is so nice and under such perfect control that exact oxidation takes place, and nothing but pure mercurial vapor passes into the condenser, and being pure is rapidly reduced to the liquid state, and upon being extracted leaves no debris behind.

An experimental run of 28 days has just been made at the Great Eastern mine, with the following results, for which we are indebted to Mr. Eames, the patentee:

Dirt run through, 77½ tons; deducting 16 tons for water contained in it, leaves 61½ tons; yield of quicksilver, 1,886 pounds. Three tons of ore produced 358½ pounds of quicksilver. Four tons of dirt from the Mount Jackson mine, also containing 20 per cent of moisture, yielded 87 pounds of quicksilver. Much of the dirt run through has been rejected as waste, although some from the Great Eastern was excellent ore; that from the Mount Jackson was all indifferent dirt. Elsewhere, it will be seen that the Mount Jackson company have ordered three of these furnaces, with aggregate capacity of 30 tons per day, to be constructed at their mine at once. The patentee has contended with many difficulties, failure often staining him in the face, and he now has our congratulations on the perfection of his invention. Mr. Eames has moved his family to Healdsburg, where his permanent headquarters are established.

Mining Decision.

The Secretary of the Treasury, under the date of Washington, February 15th, has forwarded to the Commissioner of the General Land Office his decision in the case of the Hawley Consolidated mining company against the Memnon mining company:

Sir: I have carefully considered the case of the Hawley Consolidated mining company vs. the Memnon mining company, on appeal of your decision of April 3, 1875, upon an application of the Memnon mining company for a patent of twenty-two hundred feet of the Sheridan lode, Devil's Gate mining district, Lyon county, Nevada.

The application of the Memnon mining company was filed at the local office February 23d, 1874, and with the accompanying proofs shows that the Memnon mining company has the record title to the tract claimed, and that it has complied with general and local mining laws.

Robert Apple, claiming to the act by the authority of the Hawley Consolidated mining company, on the 23d of April, 1874, on behalf of said company, filed a protest to said application, alleging that the Hawley Consolidated mining company was the owner of the premises therein described.

There is nothing in the case showing that Mr. Apple had any authority to file said protest and give notice of an adverse claim except the statement in his affidavit that he had authority, nor does it appear by his affidavit or otherwise that he is a member of the company in whose behalf he appears.

A mere allegation of authority is not sufficient; the authority to act must be shown. In the case of the Eureka mining company vs. The Jenny Lind mining company et al., decided November 24th, 1873, it was held "that the jurat to the adverse claim required by the seventh section of said Act [Act of May 10th, 1872,] must be made by the party, and cannot be made by an attorney. (Copp's Mining Laws, p. 169.) When, however, the party in

interest is an incorporated company, which can only act through an agent from the necessity of the case, this rule must be somewhat modified.

In such case the company may verify its protest by the oath of its President or other executive officer, or it may by letter of attorney appoint some proper person to act for it, who would then be clothed with sufficient power to make an affidavit. Without such authority a person not an executive officer of the company would have no right to act, and whatever he might do in its behalf would be invalid and should be so regarded.

The location under which the Hawley Consolidated mining company claims title was made long prior to the location under which the applicant claims, and from the abstract attached to the protest it appears that said company have the record title to the tract described in said location. There is nothing, however, in the protest and affidavit filed by Mr. Apple, if treated as competent, to show that the Hawley Consolidated mining company have complied with the general or local mining laws since the location of their claim or that it was a valid substituting claim at the time the grantors of the applicant made their location. It appears that the Sheridan lode and the Newport lode are substantially the same, and by the certificate of the Deputy United States Surveyor it appears that the value of the labor and improvements on the Hawley Consolidated mining company's claim on said Newport lode exceeds \$500.

This may be true; but there is nothing to show that said company or its grantors performed the labor or made the improvements. It does appear that the Memnon mining company performed labor and made improvements on its claim, and at the filing of its application was in possession thereof. The lodes being substantially the same, the surveyor could truthfully certify as to the value of the labor and improvements without knowing who caused them.

While the adverse claimant is not found in his protest to show a strict compliance with all of the mining laws and the usages and customs of mining districts, still he should show enough to make it clear that he is acting in good faith.

The abstract filed by Mr. Apple shows a record title in the adverse claimant of a tract 200 feet in width, while the diagram thereto attached and made a part of the protest represents the claim as 300 feet in width.

The nature of the adverse claim is sufficiently shown, but its extent and boundaries are very indefinite. For these reasons, without considering other apparently equally fatal to the adverse claim, I affirm your decision.

The papers transmitted with your letter "N" of July 24th, 1875, are herewith returned. Very respectfully, Z. CHAMBERLAIN, Secretary.

To the Commissioner of the General Land Office.

Butte County Mines.

For the past few weeks we have been unable, for want of space, to give attention to the mining interests of the county. While here and there nuggets of gold are found that attract attention for a short time, they form no part of the great harvest that is being gathered winter after winter, or rather year after year, for since water has been brought to the larger claims, full as much is taken out in a summer month as during the same time in winter. At Cherokee Flat the Spring Valley company are at work in rich ground with a full crew of men, and are meeting with their usual success. Last year they took out almost a half million dollars' worth of gold; this year they will run off a great deal more dirt and expect much larger returns. Mining with them is a life business. They have an abundance of ground and it is rich. The Hendricks mine in Morris ravine still yields its accustomed returns. Here are lumps of gold that are beautiful to look at. They lie thickly strewn over the bedrock. Day and night work is carried on and gold taken out. This mine, too, is very extensive. Across the river at the old West claim extensive preparations are being made to carry on the business of mining as it should be done. Three-fourths of a mile of 22 inch pipe will soon be in place, with the latest improved chiefs, to send the water against the bank with a force sufficient to melt it away like snow before the rays of a tropical sun. It is the opinion of men long acquainted with the ground, that the price of the claim—\$45,000—will be taken out during the coming summer. Right here in town, within gunshot of this office, is the claim of J. B. Hewitt, that yields a constant harvest of gold. Two four-foot flumes from the claim to the river, one-fourth of a mile, are employed all the time in carrying off the dirt from the claim and catching and holding the gold. From McSmith's claim in the mountains we have most cheering reports. He has an immense bed of gravel, part of it a river bed that is literally strewn with gold. Water was what was wanted to bring it to light. He had plenty of fall, plenty of timber and lumber, but no water. A little while spent in surveying and the thing was done. He found it in abundance and now has on the claim as large a stream as any claim in the county can boast of. Two hundred thousand dollars have been offered and refused. He has a bonanza and knows how to keep it. All through that part of the county are locations made by capitalists below, who find here the best and safest places to invest their surplus capital. Butte will yield a quarter of a million dollars' worth of gold more this year than last.—Oroville Mercury.

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed water supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rod and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24V23

FISH SCALER.—Sarah Lawton, S. F., Cal.

REAPERS.—David Palmer Russell, Dixon, Cal.

VEHICLE SPRING.—Harry K. Waterhouse, S. F., Cal.

HANDLE ATTACHMENT FOR BRUSHES.—Henry Andersou, Vallejo, Cal.

TRADEMARK.

THROAT OR BRONCHIAL AFFECTIONS.—Georgs F. Roberts, S. F., Cal.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

IMPROVEMENT IN CONDENSERS.—Chas. B. Dahlgrn, S. F. This is an improved condenser for cooling heated vapors or fumes to a temperature at which they are precipitated or become liquid and it consists in constructing the condensing chamber, either partially or wholly, of an absorbent material, which is kept constantly saturated with water, so as to produce a refrigerating effect inside of the chamber by the evaporation of the water from the surrounding surfaces. In the patent this inventor represents the application of this improvement in connection with an ordinary retort for separating quicksilver from gold and silver amalgam. The usual retort or open basin is used, with a furnace below. Upon the base of the retort is constructed a simple framework, which is capable of supporting a housing which is made of absorbent material, such as canvas, woolen, cotton or other fibrous or equivalent textile fabric which will absorb water. In this base is made a channel which extends entirely around the basin, and this channel is kept filled with water. The housing is so suspended or adjusted that its lower edge will enter the water in this channel and thus prevent the escape of any of the vapors or fumes beneath it. Above the housing are led perforated water pipes, in such a manner that they will deliver a constant spray or stream of water upon the housing and thus keep it saturated. The surplus water will flow down the sides of the housing and be caught in the channel, into which the lower edge of the housing dips, and a waste pipe is supplied to carry away the surplus water from the channel. The evaporation of the moisture from the housing will create a refrigerating action inside the chamber, inside of which the fumes are generated or delivered, so that they will be condensed against the inside of the housing and flow down its sides into the channel; or inclined planes or shelves may be arranged inside of the chamber, upon which the condensed material will settle and be directed by them into the channel. The inventor claims that a condenser of this kind can be cheaply constructed and its action will be superior to that of any of the ordinary methods of condensing vapors.

REFRIGERATOR AND WATER COOLER COMBINED.—E. K. Howes, S. F. This is a cabinet or chest, which is adapted for use, both for the preservation of meats, fruits, vegetables and like substances, and as a water cooler to supply water for drinking purposes. We described and illustrated this device in a previous issue of the Press. It is a simple and convenient arrangement of the ice and water chambers, so that they will be out the way and not interfere with the space allotted the articles or substances to be preserved. It also improves the construction and disposition of ice and water chambers by which they are rendered more convenient and effective.

HARNESSE PAD CHECK HOOK.—Wm. Davis, Petaluma. This is an improvement in harness pad check hooks, and it is intended to be especially applicable to double or single harness, in which a flexible pad with no metallic stiffening is used, and where no terrets are employed to guide and support the reins. It consists in the employment of a low, flat hook, which is riveted between the two parts of the pad trap, and is provided with a tongue actuated by a spring so as to retain the check rein in its place in the hook, and so placed as to form a guard to prevent the reins from becoming entangled with this hook.

FISH SCALER AND SCRAPER.—Mts. S. Lawton, S. F. This is a cheap and convenient hand implement for removing scales from fish and for scraping them after the scales are loosened. This handle has a head or cross bar across one end. The blade is of thin metal, one edge of which is provided with teeth similar to saw teeth, while the other edge is plain. This blade is bent in a semi-circular form, and its ends are secured to the opposite ends of the head or block, thus forming a scraping tool which can be very conveniently handled. To the opposite end of this handle is secured one end of a cord, which is of any desired length, and to the opposite end of this cord is a long pointed rod or spear. In cleaning the fish this spear is forced through the tail and the point pressed into the table underneath. Or if desired, the spear can be driven firmly into the table or board upon which the fish is cleaned, and another spear can be passed through the gills of the fish and into the table, thus firmly fixing the fish in position. The operator then takes the cleaning implement and loosens the scales with the toothed edge of the blade by drawing it over the body of the fish from the tail to the head. When the scales are loosened the implement is turned over and the fish scraped with the plain edge, thus thoroughly cleaning it. The spear and cord can be dispensed with if desired, but the work is done perfectly with them.

FRICTION CLUTCH.—Philip Hinkle, S. F. This invention provides an improved clutch, to be used where it is necessary to allow a shaft to turn freely in one direction and either wholly prevent it from moving in the opposite direction or cause it to carry with it some attachment. This clutch is intended to operate without any pressure upon the rim and without any undue or indirect strain upon the hub, its action being that of a monkey wrench. It consists of an outer rim and one side of a case which turns loosely upon a shaft, this side having a flange projecting inward from it. The other side of the case is fast upon the shaft and has an interior hub from which loose arms project towards the circumferences. These arms are notched or grooved to fit over the flange upon the opposite side, and they move loosely over it in one direction, but are cramped upon it when moving in the opposite direction. By this construction the inventor is enabled to make a clutch which acts instantly, with no slip, and he avoids the difficulty of too great a pressure upon the rim, which is liable to be hurt by the strain.

IMPROVEMENT IN PANTS AND OVERALLS.—Herman Adams, S. F. This invention provides certain improvements in the construction of pants and overalls, and consists in the formation of a pocket which is sewed upon the outside of the article, in one piece, with this button stays, which are above it, and this hack or buckle strap; and by this the inventor claims to save much expense of labor and thread which is expended on sewing on separate pieces. This pocket is cut in a peculiar shape with an extension that serves as a hack or buckle strap, all in one piece. This pocket is cut and laid upon the article in the proper position and is stretched around its edges, the stretching being continued along the buckle strap, the whole being continuous. By this construction the inventor is enabled, with proper machinery, to cut large quantities of these combined pockets, straps and stays with but little waste of material, and when the stretching is done much time is saved, and the whole presents a neat and serviceable appearance.

CARRIAGE SPRINGS.—Henry K. Waterhouse, S. F. This invention relates to an improved arrangement for combining semi-elliptic side springs with end C springs, in the construction of buggies and carriages, so as to provide a swinging, or back and forth motion, and at the same time improve the vertical action of the springs. The combination of the side and C springs gives an easy vertical action, while the motion of certain crank rods will relieve the stiffness or rigidity of that motion and give an easy swing to the body. This arrangement also connects the action of the side springs so as to produce an equalizing effect, as the spread of one of the side springs by a weight placed upon one side of the buggy body will cause the crank rods to swing outwards; and thus depress the opposite spring, thus obviating the disagreeable effect of tipping the body to this side which supports the greater weight.

ANIMAL TRAP.—A. J. Larson. This trap is essentially a gopher trap, as it is intended to meet the peculiar habits of that animal. When an opening is made in a gopher's hole this sagacious rodent gathers up a quantity of dirt in front of him and with this material as a bulwark, proceeds to close the opening. An ordinary trap in this case would only "bite dirt." This trap is intended to circumvent the gopher by giving him a chance to get his dirt into the opening and himself into the trap before it closes upon him. The animal is caught in the loop of a flexible wire, which projects into the hole from one or more spring barrels or followers and is set so as to allow the body of the animal to get into the loop. When the dirt has been put in position by the gopher he is in position to spring the trap, which draws the loop closely around his body and holds him in the firm embrace of death.

Gems and Precious Stones.

[Written for the Press by HENRY G. HANKS.]

(Continued from last week.)

Again fill the bottle with distilled water, the stones remaining inside; the same precautions must be used as in the first instance. It may be found necessary to half fill the bottle first, and to shake it well to remove air bubbles; then to fill it brimful and to replace the stopper as in the first instance. The excess of water will flow out through the little channel made with the file, leaving the bottle perfectly full; it may then be wiped dry on the outside and again weighed; mark this weight "C."

"A" is the weight of water that the bottle will hold when filled to its utmost capacity. This weight may be marked on the outside of the bottle with a writing diamond, as it will always remain the same.

"B" is the weight of the stones dry. "C" is the weight of this water which is required to fill the bottle after the stones are placed in it, and the stone.

Subtract "B" from "C" and what remains represents the weight of the water which would be left in the bottle if the stones should be dropped into it when brimming full; let this quantity be represented by "D."

From "A" subtract "D," and this weight of the water displaced by the stones is obtained, which is exactly equal in volume to the stone; let this sum be known as "E."

Now if "B" is divided by "E," the result is the specific gravity of the stones. This is very simple when it is well understood. An example will suffice to make it clear.

Let "A" = grains..... 25.36
Let "B" = grains..... 6.21
Let "C" = grains..... 27.40

From "C"..... 27.00
Subtract "B"..... 6.21

"D"..... 20.79

From "A"..... 25.36
Subtract "D"..... 20.79

"E"..... 4.57

Then—

"B" 6.21 = specific gravity = 1.3583+

"E" 4.57

When distilled water cannot be obtained, melted snow or rain water will do, and even river water will give correct results, but salt water or mineral water of any kind is inadmissible. When great exactitude is required the temperature of the water should be sixty-two deg. Fah., or as nearly so as possible.

(6) Electricity. Pliny was the first to notice this property of minerals. There are two kinds of electricity—positive and negative. It is a law of physics that bodies similarly electrified repel each other, and that bodies which do not possess the same kind of electricity attract each other. Some minerals become electrical by friction, others by heat (pyro-electric), others cannot be excited at all. There are therefore three distinct divisions of minerals by electricity alone. Where a mineral can be electrified by heat it sometimes shows the presence of the fluid in two forms. One end of a crystal may be positive while the other is negative.

Minerals which become electric by rubbing on silk or woolen cloth, will attract bits of gold leaf, or will turn a delicate electrometer. The electrometer is a simple instrument. It consists of a metallic base terminating in a fine point; on this point a delicately balanced copper wire is placed. The ends of this wire terminate in small balls of the same metal. In the test instrument the socket which turns on the metallic point is made of agate, which prevents the wear.

If a mineral excited by either rubbing or heat is presented to one of the balls it is attracted, no matter which kind of electricity has been developed. To distinguish between them the wire of the instrument must be electrified, and the character of the electricity must be known. Positive electricity is produced when glass is rubbed, from which fact it is sometimes called vitreous electricity, while any resinous substance produces negative electricity, which for that reason is sometimes called resinous electricity. Knowing these facts it is in the power of the mineralogist to charge his electrometer to suit his convenience.

To electrify the instrument it must first be insulated; this is done by placing it on a plate of glass, then place one finger on the base of the instrument, and holding a glass rod, or a stick of sealing wax in the other, rub the rod or wax briskly on a piece of woolen cloth, and place it near one of the balls without touching it; repeat this several times until the needle is sufficiently charged with the electric fluid. Then holding the rod as near the ball as possible without touching it, remove the finger and then the rod. As the instrument is insulated it will retain the electricity for some time. If you use a stick of sealing wax in charging the instrument, it is negative, if a glass rod, it is positive—suppose the former. If a mineral excited either by heat or friction is held near one of the balls, it will either attract or repel it. If it attracts, the mineral possesses positive electricity, as it has been shown that similarly electrified bodies repel each other. Should it repel, the mineral is negatively electric.

(To be Continued.)

In the Overman mine the pumps are hardly able to hold the water in check, and if the heavy flow continues at the present rate the erection of new and more powerful pumping machinery will be necessary beyond doubt.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last, President Davidson in the chair. The President has been absent ever since he went to Japan on the Transit of Venus expedition, since which time he has been in India, Egypt and Europe. As will be seen by his remarks in another column, he intends giving a series of lectures on this subject, "Engineering in Connection with Irrigation, Railroads and Harbor Improvements."

The following new members were elected: H. S. Craven, C. A. Stetefeldt, Louis Janin, James D. Hague, C. B. Dorsey, W. A. Skidmore, Hamilton Smith, Jr., Alfred Post, W. H. Hall, J. S. Curtis, Howard Schuyler, Alfred Ford and Charles Barton Hill. These gentlemen, with the exception of Mr. Hill, are all mining or civil engineers, and they propose to form the engineering department of the Academy. This department will soon be in working order.

Dr. Stout, curator of ethnology, invited attention to the sarcophagus, procured in China with great trouble and great favor, used as a receptacle for the remains of the late Minister Avery. It is constructed of teak; its sides are three inches; length, seven feet and 11 inches; breadth, three feet and eight inches; depth, two feet and eight inches. It was an extraordinary structure, differing from anything made by the Indian, and would make a valuable addition to the ethnological department, as illustrating the remarkable sarcophagi of different nations. On motion of the Doctor, he was authorized to receive this sarcophagus, either as a donation or in trust, to be retained by the Academy until such time as the relatives of deceased may desire to place it in another mausoleum.

President Davidson presented some specimens of boomrangs taken from different tribes of California Indians. They in general were very similar to those in Australia, though some minor points of difference were noticeable.

Dr. Stout moved that a vote of welcome be tendered by the Academy to their returned President. The motion was applauded and unanimously carried, it being put by the Vice-President.

General Colton brought before the Academy a proposition from the C. P. R. R. Co., to borrow specimens from the Academy to enlarge the cabinet of this railroad company, intended for exhibition at the Centennial, under the supervision of Mr. Scapham. The particular specimens desired were those of the ethnological department. This proposition to authorize the Trustees to make the loan was opposed by several members, but prevailed by a decided majority.

Wm. J. Fisher tendered his resignation as librarian. Mr. Fisher, who was formerly naturalist on the *Tuscarora* expedition, has purchased the yacht *Harvest Queen*, and has fitted up for outside work. He leaves next week on a six months' collecting tour on the Lower California coast. He will make an extended trip in the gulf, and collect all the natural history specimens available. There is quite a demand in the Eastern States and Europe for specimens from this coast, and Mr. Fisher's experience in this line is such that he will no doubt make a profitable voyage. He has all suitable appliances, such as dredges, etc., for the proposed work.

After listening to the remarks of Professor Davidson concerning his trip, the Academy adjourned.

P. H. Scott, the efficient superintendent of the Kossuth, has resigned, and Captain Sam Curtis, one of the most thorough miners on the Comstock lode, has received the appointment of superintendent of the mine.

The railroad surveyors are still at work making preliminary surveys between Reading and the Sacramento ferry, and there seems to be no doubt but that the track will be extended north of Reading the coming summer.

New and rich silver discoveries are reported in Bradshaw and Walnut Creek districts, Arizona, and some San Francisco experts are examining the War Eagle mine with a view of purchasing.

A heavy force of men are now at work upon the Walla Walla and Columbia River railroad, ballasting, strengthening and leveling the road, and putting it in good condition for running in the spring.

The Jackson mine in Mohave county, Arizona, has been sold to a Boston company for \$30,000, one-half of which has already been paid.

The Mount Jackson mining company, near Guernville, will put improvements on their mine to the value of \$25,000 during the coming spring.

The Grass Valley Union says: Richard Penhall, who was hurt in the New York mine last Saturday, died Monday afternoon.

The Blue Gravel mine at Snaker Flat, worth \$300,000 to \$400,000, will be disposed of at sheriff sale on the 16th of March.

One million feet of lumber per month is buried in the Consolidated Virginia mine.

The Ione Valley Coal Beds.

A correspondent of the *Amador Dispatch* writing from Ione City says:

Very few people outside of Ione have any idea of the immense beds of coal that underlie Ione valley and the adjacent hills to the south. S. Hart & Co. have opened two mines in these beds—one in Buckeye valley and one a mile from Ione. These two mines are six miles apart. The Ione mine has supplied the flouring mill of Hall & Son with coal, exclusively, for a number of years. It also supplies the Newton copper mine with coal, which is only six miles east of here. Several private families are using it, as it is much cheaper than wood. The Oneida has just completed a contract with the above company for 1,000 tons—the contract for hauling has been let to Brandon & Miller, whose "land frigates," with hack-action attachments (pull-backs), are now moving up the grade daily.

Messrs. Hart & Goodman are making arrangements to put an engine and hoisting works in the Ione mine which, when completed, will enable them to take out from 5,000 to 10,000 tons of coal per month. The same amount can be taken from the Buckeye mine, as they are about equal in depth and working facilities. These mines are inexhaustible and capable of supplying Sacramento and San Francisco with fuel for the next hundred years. Just think of a royalty like this in the hands of two or three men, to say nothing of the thousands of acres of pasture, supporting as it now does 16,000 sheep the year round, besides numerous herds of cattle and horses. The land contiguous to the coal mines is well timbered and water easy of access.

The Gravel Mines on Irish Hill

Are another prominent feature not to be overlooked while considering the industries and resources of this portion of the county. The Hooper ditch, lately completed, furnishes water sufficient to run six monitors (hydraulic pipes). These claims are also on land owned by S. Hart & Co., and are now being worked by them on an extensive scale, in company with A. Hayward, and one or two others, under the name of the "Ione hydraulic mining company." They employ 20 experienced miners and work three claims, with two monitors to a claim, running day and night, hattering with a constant and terrible force against a bank of gravel ranging from 20 to 50 feet in height. The noise of these hydraulic monsters is literally like the "sound of many waters." The gold is scattered through the gravel from top to bottom and in some places is very rich.

Appearances indicate a clean-up of \$10,000 per month over and above expenses.

Mining in Montana.

The *Montanian* says: There is every indication that the prospects of the mining interests of Montana are steadily improving, and that the coming years will be prolific in the development of this important industry. The apothegm that "the country is played out" is no longer the favorite utterance of the miner and prospector, but in its stead are heard the cheering reports of "strikes" and discoveries which give signs of promise. Fields which were once supposed to be valueless for mining purposes are now being prospected vigorously and in many cases with good results. The mining community have settled down to the work of discovery and development in a business-like manner, and the results of their persistent application to this pursuit are beginning to show themselves. The time is passed for the mere sinking of a hole to be called "prospecting;" the discovery of paying mines in places where hundreds of so-called "shafts" have been sunk has demonstrated the fact that such prospecting is labor thrown away, and the majority of those who engage in this business now enter upon it with a determination not to desist from their work until they are satisfied that the precious metal is not to be found in paying quantities in the locality which they have selected to work upon. It is true that "big" strikes are not reported with such frequency as in the days of '64 and '65, but the fact remains that an immense area of mineral land hitherto supposed of little worth is being opened up, which will yield a good percentage upon the capital invested and labor expended thereon. The business of mining is as any other business, and its prosecution must be carried on upon business principles, and the sooner every class of miners appreciate this truth, the sooner will their efforts be rewarded with success. We are glad to notice that in almost every section of the Territory there are indications of improvements. The placers are yielding well, and a good area of new ground will be worked or opened up during the coming season. The quartz interests are showing better than ever before, and it does not require a great exercise of prophetic faith to predict that the day is not distant when Montana will take a place in the front rank of bullion producing regions, and that those whose restless spirits urge them to abandon her for chimerical riches in other territories will have cause to regret their action. Those who adopt as their watchword the adage that "the rolling stone gathers no moss," will have abundant opportunity to laugh at the restless uomads whose faith is pinned to the proverb that the "setting hen lays no eggs."

A vein of coal of superior quality has been discovered within 30 miles of Los Angeles.

THORNE, DeHAVEN & CO.

21st Street, above Market,
PHILADELPHIA.

DRILLING MACHINES.

PORTABLE DRILLS. Driven by power in any direction, self-feed and convenient adjustment.
RADIAL DRILLS. Self-feed—large adjustable box table—separate base plate, every convenience.
VERTICAL DRILLS. Self-feeding—of new and improved designs.
MULTIPLE DRILLS. For boiler work, etc., 2 to 20 spindles, fed and returned by power or hand, together or separately.
HORIZONTAL BORING AND DRILLING MACHINES. For large pieces—with boring head, adjustable, vertically and horizontally.
SPECIAL DRILLS. For special work. Gun Blank Drills, Coal Drills, &c., built to order.

GIANT POWDER.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1.

For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2.

For medium and sandy Rock, Lime, Marble, Sulphur, Coal, Pipe Clay and Gravel Bank Blasting, Wood, etc.
Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time required for black powder.

The only Blasting Powder used in Europe and the Eastern States.

BANDMANN, NIELSEN & CO.,

General Agents, No. 210 Front Street.

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE

MOST THOROUGH TRIALS

Ever Had in the United States,

BETWEEN COMPETITORS

—OF—

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—

Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the best ever made in simplicity of construction, economical use of power, durability and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim. Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

Mining and Scientific Press,

Started in 1860, is one of the oldest weekly journals now published in San Francisco. It has been conducted by its present proprietors for ten years, during which period it has been repeatedly enlarged and constantly improved. The active and steadfast efforts of its publishers have gained for its conduct an amount of practical experience greater than any other publishers have accumulated on this coast, of a weekly journal.

The sum paid by us for this best editorial talent obtainable for our special class journal; for engravings, for interesting news and correspondence, and for printing a large-sized, handsome sheet, is unequalled by that of any other American weekly west of the Mississippi. As a PRACTICAL MINING JOURNAL it has no rival on this Continent.

It is the only MECHANICAL, and the only SCIENTIFIC journal of the Pacific States.

Miners, Assayers, Millmen, and Metallurgists in the United States should take it. Pacific Coast Mechanics, Engineers, Inventors, Manufacturers, Professional Men, and Progressive and Industrial Students should patronize its columns of fresh and valuable information.

Mining Engineers, Superintendents, Metallurgists, Mine Owners and Mine Workers throughout the world should profit by its illustrations and descriptions of New Machinery, Processes, Discoveries and Record of Mining Events.

Intelligent thinkers throughout the land, in high or humble situation, who would avoid literary trash for genuine information, should SUBSCRIBE AT ONCE.

Number 12.

The Foot Lathe.

The development of a taste for the mechanic arts has been very marked within a few years past. Students, clergymen, gentlemen of leisure, and others of sedentary habits, have sought relaxation from mental and physical strain in this, to them, agreeable recreation. That which to the mechanic is wearisome through its necessity, readily becomes a pleasant and, at the same time, useful pastime. Many of our most active business men have a workshop fitted up at their homes, in which some of the most costly tools are kept, where, after the vexations of a day's business, they can unbend their minds and relax their muscles in fashioning some tasty article as a gift to their family or friends. Such gifts are appreciated the more, both by the giver and by the recipient, for the reason that they are the result of hours of patient labor.

The most important of the tools required in developing this taste—in fact the first and only necessary one—is the turning lathe. By the use of proper appliances it can be adapted to an almost unlimited variety of uses. To turning articles of wood or iron of every conceivable shape, to drilling, to engraving, to sawing, and in fact to almost every description of work.

When the necessary motive power cannot be obtained elsewhere, the operator can supply it by means of foot power. The manufacturers of the Eagle foot lathe seek to supply with this implement a want long felt for a foot lathe of perfect construction. By devoting a manufactory exclusively to this work, supplied with expensive machinery and every convenience, such as in the system of the manufacture of fire arms, etc., the manufacturers, W. L. Chase & Co., of New York, have succeeded in producing, at a moderate price, foot lathes interchangeable in all their parts and of good style and finish.

We illustrate on this page three forms of the Eagle foot lathe, of which a number of sizes are made. Lathe No. 1 swings six inches and turns twenty-two inches long. This lathe is perfectly adapted for most kinds of turning in wood or metals, also drilling, boring, polishing, sawing, etc. The legs, bed, balance wheel, cone pulley, head and tail stocks and treads of this lathe are made of cast iron, and the spindles are cast steel. The spindles run in boxes which can be tightened up as they wear. The balance wheel weighs forty-two pounds and has three sizes for change of speed, and by varying the motion of the foot, will give a sufficient compass of speed for the size of the lathe. The hand rest, slide rest, and tail stock are held in place by cam fastenings. The running parts are truly balanced and noiseless. The lathe is very strong and free from any vibration, and combines strength and durability without being heavy or clumsy. This lathe is painted and varnished in plain but good style, and has a black walnut bracket shelf attached to the bed. The pieces which accompany it without extra expense, are two pointed centers, one spur center, face-plate turned and polished, three T-rests, one nine inches, one six inches, and one three inches long. The center in the tail stock is loosened when the spindle is drawn back far enough for the traversing screw to touch it. The ways of the bed are planed true, and are thirty-six inches long. The circular and gig saws which fit this lathe are simple and convenient. The treadle is provided with a joint to avoid injury to the feet, should they get under it while in motion.

Lathe No. 4 swings 10 inches diameter and turns, as ordinarily made, 31 inches, although the length of bed can be varied up to six feet to suit purchasers. This lathe is better adapted to larger and longer work than the others, and at the same time will do smaller work as well. The balance-wheel has three sizes for change of speed, giving efficient compass of motion by the variations of the foot. The engraving represents No. 4 back geared. The legs, bed, balance-wheel, cone-pulley, head and tail stock and treadle of this lathe are made of cast-iron. The spindles are made of cast-steel, with

hollow and conical hard-wood bearings, finished and polished. The ways of the bed are planed true, and are four, five or six feet long, as may be desired. The tail-stock is so constructed that it can be set over for taper turning or irregular pieces. The hand-rest and tail-stock are held in place by cam fastenings. The circular and gig saws are used on this lathe. The treadle has a joint to prevent injury to the feet, should they get under it. The crank-shaft of this lathe runs on steel points, making it easy running. This lathe is ornamentally designed, painted, varnished and finished in superior style. Brackets and shelf are attached to the back, or beneath the bed. The lathe is built both with single and back geared head-stock.

EAGLE FOOT LATHE NO. 1.

In addition to the lighter lathes, to be operated by foot-power, these manufacturers have arranged one similar in every respect to those in use in manufacturing establishments, having self-acting, feeding and screw cutting apparatus, back gear in the head for slow speeds, etc. The cut gives a fair representation of the style. Swings ten inches diameter, turns from 28 inches long to 40 inches long, according to length of bed; has hollow spindle, conical bearings, hardened steel boxes, and set over tail-stock for taper turning; cuts right and left hand threads of from four to 80 to the inch.

The manufacturers have a simple little device of great utility (which is readily attached to this lathe,) for cutting gears, from the smallest practical size up to nine inches diameter and one inch face. The belts used are Underhill's patent belts of a peculiar shape, to which cone pulleys are adapted. With these lathes a number of appliances increase their usefulness, and are made by the same manufacturers. The slide rests are provided with two slides placed at right angles with each other, carrying a tool which may be drawn back and forth or sideways by means of screws, allowing any position for the turning tool. It is worked by hand, and will turn straight or tapering, and faces or square up surfaces. In addition there are drills, drill-chucks, circular saw, gig saw, geared chucks, lathe dogs, drill collet, bit shank collet, drill pad, scroll saw, crotched center, back and center rest, etc. They also manufacture a hand planer as an auxiliary to the lathe. These tools are not by any means toy machines, but first-class implements, adapted to all variety of work. The agents in this city, Messrs. Dnnham, Carrigan & Co.,

No. 107 Front street, have a number of these machines on hand at their store, where they can be examined by those interested; or by addressing them a descriptive circular will be sent, which illustrates and describes the various styles. Those, however, who have the opportunity will see many things of interest in this line by visiting the store.

The State Geological Survey.

The Senate Committee on Finances on Wednesday night had under consideration the two bills, one by Graves and the other by Hendricks, for the completion of the Geological Survey. The bill by Graves appropriated

EAGLE LATHE NO. 4, BACK GEARED.

\$4,000 per month and looked toward carrying on the work much after the manner in which Professor Whitney proceeded with it. The bill by Senator Hendricks only appropriated \$8,000 per year and confines the operations under it to the sphere of economical geology. After a long consideration of the subject the Committee came to the conclusion that the present condition of the States' finances will not warrant any expenditure in this direction, and will therefore report against the passage of both bills.

This is much to be regretted, although the friends of the measure had only slight hopes that it would pass this session. The miners will be the greatest losers, as we feel confident that had Mr. Good-year, who had the best chance of being State Geologist, taken the matter in hand, under proper auspices, he would have published many facts of interest and value to the mining community. It is a great pity that a work like the State Geological Survey, on which so much money has already been spent, should remain incomplete for the want of a small appropriation to work up material already gathered.

The situation at Fort Pease, Montana, was, at last accounts, more desperate than ever. Between 2,000 and 3,000 hostile Sioux are constantly swarming throughout the country, preventing the garrison from venturing forth for game or even fuel, being even reduced to the extremity of burning their cabins inside the stockade to warm themselves and cook their food. Nine men, absent for some time up the Big Horn, had not been heard from, and it is feared that they have been murdered by the Sioux.

Mining Engineers at the Centennial.

The Centennial exhibition at Philadelphia will draw together, among other classes of persons, a great many mining engineers from various countries, and we are glad to see that the American Institute of Mining Engineers has taken steps to properly entertain those who come from abroad. The committee having in charge the reception of foreign mining engineers and metallurgists coming to this country to visit the Centennial, have secured rooms at No. 1,123 Girard street, Philadelphia, which will be open to guests and members of the Institute from April 1st to December 1st, 1876.

These rooms will be in charge of a secretary of the committee and employees, and will be furnished with all the technical periodicals, with conveniences for writing and parlors for meeting and conversation. An address book will be kept by the secretary for recording the names and addresses of the members of the Institute and of foreign engineers and metallurgists who come to the exposition. All members of the profession coming, introduced to the Institute or its members, will receive a card which will entitle them to all the privileges of the rooms and to attend and take part in the meetings of the Institute.

The annual meeting, which takes place in May, has been adjourned to the last of June, in order that they may have the pleasure of having the largest possible number of foreign engineers present. It will be held in the Jury Pavilion of the exposition.

The committee propose to give conveniences at the rooms for the storing and forwarding of baggage, specimens and packages which their guests may have collected in any part of the country and desire to have kept in a safe place until they are ready to take charge of them. They also propose to prepare schedules of information relating to the leading mining and metallurgical industries of the country. In case any one should desire to pursue a special line of enquiry the secretary or the members of the committee will take great pleasure in forwarding such investigation. It is designed also for those members of the profession who have but a short time to remain, to group for survey the special objects which they may have an interest in studying in the exposition. The secretary is instructed to furnish to those who desire to make the acquaintance of specialists in this country, letters of introduction, which will secure for them, not only admission to the works which they desire to visit, but also the acquaintance of technical gentlemen in all parts of the country. The Institute hopes in this way to furnish its foreign guests, not only with special information, but also to put them in the way of getting at a general survey of the whole of the mining and metallurgical industries of the United States.

The Committee consists of Eckley B. Coxa, J. S. Alexander, Thomas Eggleston and E. W. Raymond. They solicit from engineers and others on their coast and elsewhere, copies of proceedings, reports, maps, surveys, drawings of machinery, etc., to be placed on files in the rooms of the Institute. Contributions of this kind can be sent to the committee at the above address, or to any of the following named members of the Institute in this city: J. D. Hague, Henry Janin, Louis Janin, William Ashburner, and John H. Bealt; or W. S. Keyes, Eureka, Nevada.

THE PRESS AT THE CENTENNIAL.—We have received a circular, issued by G. P. Rowell & Co., describing a plan for exhibiting the serial publications of the country at the Centennial. A beautiful building will be erected, in which the thousands of magazine and papers will be shown. It is a happy idea, and many a visitor from far off regions will feel as though he had met an old friend as he sees his favorite newspaper spread its well known face before him. We heartily approve the plan. The Press will be there, ready to receive its patrons and friends in the elegant newspaper edifice.

SCREW CUTTING ENGINE LATHE.

CORRESPONDENCE.

West Mountain Mining District.

EDITORS PRESS:—As doubtless many of your readers are interested directly or indirectly in mining affairs in this part of Utah, I will give a concise statement of the situation. During the past winter many locations previously considered of doubtful value have been developed into first-class mines. Not first-class in comparison with the Consolidated Virginia, but otherwise truly first-class. Among the smelting ore mines, the Montreal has become as good as the best in the district; is producing 30 to 40 tons per day, with a capacity of 75 tons per day—worth about \$50 per ton on the dump. Ore mostly a greyish carbonate of lead.

The Nez Perce mine, in the same vicinity, is much the same in quantity and value.

The Sacramento, which had lain idle for six or eight years, has recently become a good producing mine.

The Decomposed is owned by some colored men, who had run a tunnel 300 feet directly away from their vein, and become about discouraged; at the advice of the writer they began back, and within 10 feet of the surface struck ore in large quantity, which has given a different cast to their countenances.

The Grecian Bend, which, a few months ago, looked as ridiculous as the ladies' fashion from which it derived its name, is becoming very promising in ore production. As many more, the names of which I cannot recall, within a few months past have become profitable. The older mines are retaining their good repute. In regard to milling ore veins, the discovery of which I wrote you in my last communication—the frequency of their discovery and their richness is creating considerable excitement.

The first of the kind found, the Mayflower, is being sunk upon, and is developed to the depth of 600 feet. The ore is mostly of rather a friable consistency, not much harder than chalk, and is worth in gold and silver about \$35 per ton. The vein is from five to 10 feet in width. The Accident, two miles from the former, last week struck a three-foot vein of ore, assaying from \$500 to \$900 per ton in silver and gold! Another in the same vicinity, at a depth of 40 feet, are on a four-foot vein assaying \$75 per ton.

Many discoveries of this kind have heretofore been made by persons looking for galena, and were regarded as of no account. Nearly all of these good finds were made by poor fellows who need assistance from the moneyed men. Although we are making great efforts to increase the supply of gold and silver, we see none of it after it is whirled away from us in the shape of bullion. It is too bad that we cannot handle and rattle it in our pockets after having provided it to be manufactured into the shiners. Greenbacks are becoming odious and odoriferous. Yours, WILLIAM TEAL, Bingham, March 2d.

The Black Hills.

The following letter of Mr. Silas Reed was recently published in the *St. Louis Globe*. He seems to have had some experience of the country, and gives a good idea of it in his letter:

I see so much said and written of late about the Black Hills of Northeast Wyoming that I feel inclined to jot down a few suggestions in regard to the rush of emigration there, which is now so fully inaugurated. I have spent the last six summers in the Rocky mountains, and have ascended every considerable mountain in Wyoming—and also many of Colorado, Utah and California—except where the presence of Indians forbade it.

The people of the great valley of the Mississippi have only the faintest conception of the splendid climate, the sublime scenery and the unlimited mineral wealth which exists there.

In my six annual reports to the Commissioner of the General Land Office, I have given a summary view of the geology and mineralogy of the mountains and plains visited, and may therefore state that I believe the mineral wealth of Wyoming will, when equally developed, show to be as great as that of Colorado.

The purpose of this note is to warn the young men of the country from rushing to the Black hills in too great numbers this spring, and without due preparation and thorough outfit for the work and hardships before them. The fear is that the gold-bearing surface within the Black hills is not large enough to repay the labors of the thousands and tens of thousands who are rushing thither this season.

A letter just received from a citizen of Cheyenne, who is well informed as to the numbers going, states that 15,000 men and miners will be in the Black hills before midsummer. This would not be too great a number, if it were not for the fact that these "hills" are literally in the center of the largest and most warlike tribes of Indians that roam over the great plains and mountains.

Red Cloud and Spotted Tail, with their bands, are located at the southern extremities of these hills, and the wild "haves" of other more warlike tribes flank the hills on the east and west and north, and will prevent the grazing of cattle and the cultivation of the soil around the borders of the gold region. Hence, nearly

all the supplies will have to be transported from Cheyenne, a distance of 200 to 250 miles, right past the camps of Red Cloud and Spotted Tail.

How easy it would be for these Indians to cut off or destroy the supply of food at any time, if so decided upon by them.

The real winter months do not end at the eastern base of the Rocky mountains until late in March and April. The cold is not so great, but there is more snow and wind. This will hold the Indians in check until about the 1st of May. After that, every man will need his Henry rifle and plenty of ammunition, and a quick, watchful eye and a brave heart to save his scalp.

These Indians are smarting for vengeance, because the United States Commission would not agree to pay them \$6,000,000 last fall for the hills. They will avenge their supposed grievances on the miners as soon as the new grass comes up, in May.

Gen. Crook is already moving, or about to move, a large army in the Indian country, along the eastern base of the Big Horn mountain, with scouting parties branching east towards the Black hills, and north toward the Yellowstone river. I was informed by Gen. Ord, when in this city a few days since, that the movements of Gen. Crook were doubtless intended as a restraint upon the Indians—a warning to them not to attack the mining camps, except they court war and that good whipping which the wild, fighting young men of the Sioux tribes will doubtless get before they live in peace with the miners and herders of that splendid valley bordering the Big Horn mountain and Yellowstone river.

All Wyoming and Montana rejoice at the certainty of a speedy occupation of gold mountains and rich grazing and agricultural valleys lying between Fort Laramie and Fetterman, at this end, and Bozeman and Helena, at the other. These territories will now very soon have a pathway "across lots," from Cheyenne, via Fetterman on the North Platte, the eastern base of the Big Horn mountain and up the valley of the Yellowstone to Bozeman mountain.

The distance from Cheyenne to Bozeman, on this line, is very little, if any, greater than from Bozeman to Corinne, on the Central Pacific railroad, nearly 600 miles west of Cheyenne. This road is a cut-off along one side of the great triangle which was attempted to be opened both by the Government and people in 1867-8, by the erection of expensive forts through the Indian country between the North Platte at Fort Fetterman, and the Big Horn river, near its confluence with the Yellowstone, at the crossing point of the former, where Fort Fetterman was erected.

Fort Phil. Kearney was located near the head of Tongue river, and Fort Reno on the headwaters of Powder river.

These streams both rise in the eastern slope of the Big Horn mountain, and bring down gold. The Montana miners are looting upon them.

The Indian massacre of about 80 soldiers, one morning in 1868, at Fort Phil. Kearney, caused the surrender of the United States Government to the Sioux Indians, and the abandonment of all three of the forts.

It was a fatal mistake toward the new settlers of those territories, but will now soon be remedied, through the presence of General Crook and the great army of miners now taking possession of that magnificent new country.

The future cities along this assured line of travel from Cheyenne to the Yellowstone, and thence to Bozeman, Montana, will be at or near the sites of the three abandoned forts, and at or near the mouth of Clark's fork, a gold-bearing stream which enters the Yellowstone from Wyoming, below the falls of the latter.

There is one great and gratifying fact connected with the present rush of miners to the Black hills. When too many collect there to work profitably the limited area of placer deposits they will find an ample and ready outfit by going west 75 to 100 miles to the Big Horn mountain, which has five times the gold-bearing surface the Black hills, and is a part of the main range of the Rocky mountains.

The Indians do not frequent that mountain in very large numbers, even in summer, and a reasonable force of miners would be far safer there than in the Black hills.

This mountain is crescent shaped, with its center cut through by the great canon of the Big Horn river, and its southeast point reaching to within 40 miles of old Fort Casper (well known to early California emigrants), on the North Platte, west of Fort Fetterman. Its southwest arm forms the mountain east of Yellowstone lake, giving rise to Clark's fork and other rich gold-bearing streams, and finally joins the great Wind River range (the main crest of the Rocky mountains), northwest of Fremont's peak.

The southeastern end of this Big Horn mountain is very safely and easily reached. The route is from Cheyenne to Fort Fetterman, thence up the North Platte along the old emigrant trail to old Fort Casper, and thence northwest 40 miles over a rolling, grassy country, to the headwaters of Powder river and the Big Horn mountain.

Were I a young man, and anxious to plant myself in the largest unoccupied gold field on this continent, I would enlist 100 brave, hardy, resolute and ambitious young men, from farms and workshops, to join me in the great work of opening up the gold and silver resources of the Big Horn mountains, and founding two or more cities equal to Denver in the early future, at their base.

Somebody will begin this great work very soon, now that General Crook is on hand with his protective force to see that the miner, unmolested, unlocks the great treasure hoard there, and is not driven away by his own Government, as has been the policy heretofore.

The Wind River valley, on the west side of this mountain, is the home of the friendly Shoshone Indians, where fine wheat and other cereals are raised, and can be had in great abundance.

These Indians would hail with great joy the advent of white settlers in this valley (see farmers) and miners in the Big Horn mountain, as that would re-inforce them against their enemies, the Sioux, on the east side, toward the Black hills.

A narrow-gauge railroad on this route has been discussed by men of Wyoming and Montana for several years, and is certain to be built from Cheyenne, via Fort Fetterman, to the Yellowstone, as soon as the Indians are overawed. It should be commenced immediately. Not a month should be lost in hesitation by the men of Wyoming and Montana.

Mining Affairs in Idaho.

From a recent number of the *Owyhee Avalanche* (Idaho), we take the following, which will give an idea of the mining situation on War Eagle mountain:

To the eye of a casual observer the status of affairs on War Eagle mountain at the present time does not reveal a very encouraging picture, although the ups and downs of mining camps present their bright and dark reflections at intervals, and it is possible that we are just now passing through the ordeal known as "the dark hour before the dawn," and having got down to bedrock an ascent of the up grade may give us opportunities to retrieve the errors of the past and lay a better foundation than ever for future operations. It is meet that we should take in sail and keep close to shore. The old residents of Owyhee have passed through some trying ordeals in the past, and although the prospects at present are not as bright as they might be they are not entirely discouraged at the outlook. It is not an encouraging sight that is presented to the eye on wandering over War Eagle mountain to see such costly mining works as the Mahogany, Illinois Central, Oro Fino, Red Jacket, Silver Cord and War Eagle, erected at an expense of several hundred thousand dollars, lying idle and unproductive when it is conceded that under judicious management all these mines might be turning out hullion and yielding handsome dividends to their owners.

Will the men who have invested so much capital here in aiding to develop the mines allow these valuable works to go to ruin? We believe not. It is not for their interest to do so. The curse of the camp may almost be summed up in one word—mismanagement. Take for instance such a mine as the Illinois Central, which two or three years ago was managed by a gentleman who kept a moderate force of men at work and so conducted operations as to make the mine yield dividends for its owners instead of assessments being the rule. Every man who knows anything about such a mine as this knows that it can be taken hold of again and worked successfully. Extravagance, irresponsible management, unnecessarily expensive works, employing a much larger number of hands than can be judiciously worked, have all combined with other causes to bring about the present state of things. The mines have not been worked on their merits. They have in many instances been used as a cat's paw to further the interests of stock gamblers, and worthless dunghills of superintendents have been forced upon us and made to connive at rascality perpetrated in one form or another. The miner has been defrauded of his hard earnings. The mechanic has suffered, and every merchant and business man in camp has been made to feel the disastrous effects of such a ruinous policy. At "both ends of the line" this loose and dishonest system of managing the business has received more or less encouragement and people here have submitted to the outrage and had their rights trampled upon until "forbearance has ceased to be a virtue." We still have faith in the merits of the camp, but a "new deal" is called for at the present time. Give us practical, efficient and honest men to control the mines and all will be well. There is not a mine to-day on War Eagle mountain that under an economical and judicious system of working could not be made to do a profitable business, and now that we are about down to bedrock it behooves every man interested to use all the personal influence that he possesses in the way of securing such an honest and efficient management as will cause all to feel that the resumption of operations under different auspices shall have a brighter outlook in the future than we have been accustomed to speculate upon in the past.

A RICH STOCK BOARD.—The San Francisco Stock and Exchange Board, better known as the "old board," have declared a dividend of \$200 per certificate, payable immediately to each of its 100 members. The total amount to \$20,000. The resource of the "old board" have swelled to quite a respectable figure. It is officially stated that the building fund, \$300,000 coin, is in hand. The lot upon which the building is being erected is already paid for (\$150,000), and there is left beside \$200,000 in the hands of the Treasurer. The income from receipts is \$30,000 per month, enough to pay a monthly dividend of \$20,000 and carry over \$10,000 monthly. A seat in this board is now valued at \$30,000.

A New District—Aurora.

A correspondent of the *Silver State*, writing from Cornucopia, gives the following about Aurora, a new mining district in Nevada:

This district is located west of here, and near the Winnemucca and Cornucopia road. It was first noted by a sheep herder in 1871; but locations were not made, the sheep herder thinking there was nothing in it. W. B. Vanx, an old prospector, well known in Caribon, Idaho, Montana, and the discoverer of the celebrated Rabbit Creek district, in the Salmon river country, Idaho, and one of the party of five that traveled 500 miles on snow shoes in the dead of winter from the head of Salmon river to the head of Cedar creek, and the lucky discoverer of the Last Chance mine on Quartz creek, on the Missoula river, in the same district, discovered this new district of Aurora.

In May, 1875, some parties claim they knew all about it; but it is all false. Nothing was known about it until Vanx & Co. prospected it this last summer, fell and winter, and brought it into notoriety. Billy Vanx and Bob Hutchinson are indomitable; two of the best prospectors in the country. They have formed a new district and called it "Aurora," adopted mining laws according to law and acts of Congress of the United States. They have located, first, the Aurora, croppings of which assay \$201 per ton, assessment work all done; then the Pride of the West, four assays as follows from the croppings, \$1,007, \$1,012, \$750, \$2,000; next, the Savage, a well defined ledge, no assay yet made, but a splendid prospect is shown; next, the Washington, the float assays \$500 per ton; this is a very large ledge—face simile of the Leopard; next, the Florence comes, this is similar to the Washington, which it joins on the south; then comes the New El Dorado, a splendid ledge, and the same character as the Washington, can be traced for a mile and a half, and runs directly towards Cornucopia, and is in the same belt or porphyry range, is 18 feet wide on top; then we see the John Adams, which joins the Washington extension, a well defined ledge; then the Thomas Jefferson, a well defined ledge, blind at first, but it shows good ore of a chloride character, and would astonish the old chloriders of Mountain City and Cornucopia in their palmy days. Thus, Mr. Editor, from the sources from which I glean information I must say that Aurora stands at the head of the heap. The boys say they will ship considerable of their croppings to the Humboldt reduction works, and then they think they can make it pay.

Build the road, make it passable, and you can bet that the northern portion of Elko county will look to Winnemucca as its objective point on the railroad. Build the bridge and the miners of Aurora intend to give freight teams all the ore they can carry to be worked at Winnemucca.

Copper in the Foothills.

All old settlers remember, some with pleasure and many with sorrow, the great copper excitement that existed in the foothill region from Mariposa to Tehama, some years ago. The excitement was occasioned by the discovery of numerous ledges of rich copper ore. But when the second discovery was made that this copper ore could not be made to pay with the facilities at hand for working it, the excitement suddenly died away. Many, though, asserted then that in time, when improved appliances for reducing the ore could be had near at hand, instead of in far off Wales, the nearest then, these mines would become remunerative. That time, it seems, is about upon us. Successful reduction works have been erected in different localities, and, as a consequence, the interest in copper, from Conneropolis to Spenceville, along the foothills, is fast increasing. Spenceville lies in Nevada county, just across Bear river, which divides that county from Placer. A correspondent, writing from there to the *Marysville Appeal*, under date of February 21st, on this subject, says: "I hope you will give me room to inform the readers of your paper in regard to the copper mines in Spenceville and vicinity. Of the San Francisco company, whose works are located in Spenceville, and under the management of Mr. Aaron, great hopes are entertained in their success. The company expect to be shipping copper in about one month. Their ore is worth seven per cent., and they have 2,000 tons out and already roasted, which they intend to put through the leaching process as fast as their works will allow them. The Centennial works, located near Hacktville, are owned by Cantfield & Bitoer; the works are under the management of Mr. Cantfield, who is a man of great ability and a scientific copper miner. His process is beyond a doubt a success. It is new and known only by him. The Green and Western Star will be opened in the spring; their ore will go 10 per cent. The Last Chance mine is the richest one in the district, and its ore goes from 15 to 30 per cent. This mine is owned by San Francisco capitalists. The company intend to open their mine in the spring. There are hundreds of good mines in this district that some day will be opened. All that is wanted to make this the best mining district in the State is capital.

The California and Brunswick mills will soon be started on ore from the California mine. These two mills alone, running on the rich ore of the mine, are expected to be amply sufficient to make steady dividends, the California mill alone having crushed 8,000 tons of Consolidated Virginia ore during the month of February.

SCIENTIFIC PROGRESS.

The Practical Uses of Light.

Dr. Crookes appears indefatigable in his endeavors to turn his recent discovery of the motive power of light to some practical advantage. He recently read a paper before the London Institution on the "The Radiation of Light," in which he alluded to some possible practical uses to which his discovery might be applied. He suggested that the torsion balance, which he has used for testing the amount of action caused by the approach of light to it, should be employed as a test for the purity of our gas supply. First he would test the quality of the standard candles used, which it is known really vary very much when that variation is regarded from the standpoint of scientific accuracy. Then, with the torsion balance, he would test the comparison between the gas and the standard candle, the slightest motion of the balance being capable of being recorded by the index scale on which the reflecting mirror shines. The other suggestion was the application of the rotating apparatus to meteorological purposes. He has arranged the windmill rotating wires with pith balls, so that they carry round a small magnet suspended beneath them. Their rate of rotation depends on the amount of light that falls on them.

Near the magnet attached to them is suspended another magnet, which oscillates as the attached magnet presents alternately its north and south poles. This oscillation is arranged to make and break an electric circuit, which, by a wire that may be of any length, is connected with a recording Morse machine worked by clock work. Each revolution of the rotating pith balls is thus recorded by a pen of the Morse on a strip of continuous paper, and so a self recording account of the amount of light falling at any place may be kept.

In our present meteorological records, Dr. Crookes observes, we notice heat, rain, and pressure of atmosphere; but light, the most important influence, both as regards health and agriculture, is neglected, because not till now have means of measuring it been known.

THE ABSORPTION OF HYDROGEN.—The well known French chemist, M. Gaillardet, has continued his researches into the absorption of hydrogen by iron, with some interesting results. It appears that when an iron plate is attacked by sulphuric acid being poured over it, a portion of the hydrogen produced is absorbed by the metal, and the pressure of the gas which is accumulated between two iron plates, welded together, is sufficient to counterbalance a column of mercury 13½ inches high. This singular property of hydrogen, which has also been confirmed lately by the investigations of M. Sevois, is regarded by the latter as a most interesting discovery, and he attributes to the presence of carbonic oxide, or hydrogenized gas, the brittleness which some classes of iron manifest when an attempt is made to draw them into wire, a fact well known to workers in this metal. It is also found that when decomposing by the galvanic battery a solution of chloride of iron to which sal-ammoniac has been added, metallic iron may be collected at the south pole in the form of a brilliant wart, brittle and often hard enough to scratch glass. This iron after being washed evolves, either under water or another liquid, numerous bubbles of gas, which is pure hydrogen. When freely exposed to the air, galvanic iron loses only a portion of its hydrogen; under water, especially water heated to 140 or 150 deg., the hydrogen is given off with violence. As to the quantity of hydrogen iron thus treated can take up, it seems that, for one volume of iron, the amount is 200 volumes of gas; in weight, 13 parts of iron absorb one part of gas. When a lighted match is applied to this iron saturated with hydrogen the gas burns like alcohol.

SCIENTIFIC BALLOONING.—In our enumeration, last week, of the practical and scientific benefits derived from ballooning, we overlooked one very important and very remarkable discovery, due to Gay-Lussac, in regard to the continued increase of electric tension as we ascend into the upper regions of the atmosphere. The air there has been found to be much more highly charged with positive electricity than that near the earth. The distinguished scientist named found that the increase of tension was in proportion to the elevation; hence, it was inferred that he was far from obtaining the maximum of tension. His observations indicate that we may consider the globe as enveloped, at great heights, with a vast, strongly electrified mantle, which is in constant motion from the equator towards the poles. In its passage thitherward, the electricity is constantly being drawn off, in small quantity, by the incidental action of storms (which largely derive their electricity from this source), the balance reaching the earth through the silent and mysterious medium of the aurora borealis.

In a drop of water obtained from a single snow-flake and magnified 500 times were found pieces of coal, fragments of cloth, grains of starch, sandy matter and an immense variety of other substances, not a fragment of which exceeded the three-thousandth part of an inch in diameter.

An Ice Rink at All Seasons.

A dangerous rival to the asphalt skating rink is announced. The wheel-skates are, after all, only an alternative. Locomotion on them is neither so free nor so pleasant as with an iron blade upon ice; and we are now informed that after five or six years of experimenting in Chelsea, Professor Gamgee has at last got at the secret of making an artificial ice sheet, capable of being maintained in perfect condition for skating from one year's end to the other. A similar plan has been patented, and is about to be put into practical operation in Glasgow, the object, as described in the patent specification, being to refrigerate and cool floors so that water carried thereon may be frozen with an even surface for skating and curling. Similar experiments to those of Mr. Gamgee have been carried on at the ice works at Garnethill, Glasgow, by their manager, Mr. Rae, who is one of the patentees of the invention referred to, and at the works of Messrs. Seddley & Co., Liverpool, and there is said to be no possibility of failure. The process is the same as that used in the manufacture of ice for dietetic purposes. It is very simple. A mixture of salt and water, cooled with ether in refrigerators, is made to pass between iron plates about half an inch apart. The upper plate is covered with a thin layer of water, which soon freezes and forms a dry, keen skating surface. At the rink which it is proposed to establish in the fashionable quarter of Glasgow, a new sheet of ice will be formed every morning; but if in the course of the day it becomes rough, all that is necessary is to sweep off the powdered ice, flush the rink with water, and in 20 minutes a new surface, fresh, firm and glassy, will be produced. This surface will also be more elastic than asphalt, and consequently less dangerous in case of a fall, and there will be neither dust nor sloppiness. It is not expected that the temperature of the ball will be much affected by the ice, but it is alleged that, if necessary, it may be warmed in the usual way without detracting from the efficiency of the rink.

Occluded Hydrogen in Explosive Antimony.

When chloride of antimony, made according to the directions of the German pharmacopoeia, is decomposed by a single cell of a Bunsen battery with a resistance of about 800 feet of copper wire (the positive electrode being formed of a massive piece of cast antimony, and the negative electrode of one or more fine platinum wires), in three or four days the platinum wires will be covered with a metallic film with a silver luster. The slightest scratch, or a spark from an induction machine, will cause it to explode with a loud noise and flash, and the evolution of a great quantity of white vapors. This was first observed by Gore, and it was supposed that the film consisted entirely of pure antimony in a peculiar allotropic state. Some years ago Professor Bottger proved experimentally that the apparently metallic film on the platinum wire did not, by any means, consist of pure antimony, but beside antimony there was in it no inconsiderable quantity of chloride of antimony, which could be proven by throwing a little distilled water on the disrupted mass while glowing; a copious white precipitate of basic chloride of antimony was formed, which could not occur if the said film consisted only of metallic antimony.

The most recent observation of Professor Bottger on this remarkable electrolytic product is the discovery therein of occluded hydrogen, possessed of the same reducing properties as that contained in Graham's alloy of palladium and hydrogenium. If a platinum wire, freshly coated with the so-called explosive antimony, is placed for 10 or 15 minutes in a very white aqueous solution of ferrocyanide of potassium, the latter will be partially converted into ferrocyanide of potassium, a property which chemically pure antimony, free from arsenic, does not possess.—*Sci. American.*

ANNUAL VARIATIONS OF TEMPERATURE.—Prof. Loomis and other authorities assert that although the annual mean temperature of a place varies, the difference between the coldest and the hottest year seldom exceeds 10 degrees, and this statement is supported by the following evidence:—"At New Haven the hottest year which has occurred in a period of 86 years was that of 1828, and the coldest year was that of 1836, the extreme range of the annual temperature in 86 years being 6.30 deg." The meteorological registers kept by President Day and Stiles and by Dr. Monson and others for the 86 years between 1778 and 1865 were rigidly inspected and reduced by a committee of the Connecticut academy, who reported these records as proving the following facts: "That for all those years of the century no permanent change had occurred in the average date of occurrence of the last frost of spring or of the first frost of autumn, nor in the time of the first snow of winter, or the last snow of winter, or in the average date of the flowering of fruit trees, such as the peach, cherry, etc." This was not inconsistent with the reports in the same records of great extremes of heat and cold temporarily experienced at intervals. Such extremes are well known in authentic history all the way up the Christian era.

"The Mass of Mars" is the subject of an investigation by Prof. Asaph Hall, of Washington.

SUNLIGHT ON FLORAL DEVELOPMENT.—In a German periodical on botanical biology, Dr. A. B. Frank has a paper on one-sided acceleration of the flowering of some catkin-like plants, showing that this is due to the action of light on the sunny side. In this respect American investigators are ahead. Some years ago a paper on this subject appeared in the proceedings of the Academy of Natural Sciences of Philadelphia on the same subject and making the same explanation. The catkins of some willows were shown to have their stamens develop first on the sunny side; and this growth toward the sun had the effect of giving the apex of the catkin an inclination toward the north. The American observer went further than the German one, and included the flowers of the early-blooming magnolias. These also grow most rapidly on the sunny side.

ELECTRICITY AND LIGHT.—A new relation between electricity and light has been announced by Dr. Kerr, of Glasgow, who finds that when glass, which in its normal condition is a singly refracting medium, is properly subjected to the action of intense electrostatic force, it assumes a new molecular structure and thus acquires the property of double refraction. A Ruhmkorff's induction apparatus was employed and a block of plate glass served as the dielectric medium, while polarized light was transmitted through the glass in a direction perpendicular to the lines of electric force. Under these conditions the glass acts as though it has suffered compression along the lines of force, or, in other words, it becomes a negative uniaxial medium. Similar results were obtained with other dielectrics, the action of resin, however, being contrary to that of glass, or positive.

MECHANICAL PROGRESS.

Sixty-Foot Rails.

We mentioned a few weeks since the fact that a few 60-foot rails had been rolled as a matter of curiosity, and to show the possibility of the production of rails of such great length. Since that time the Edgar Thomson steel works (Pennsylvania and New York) have recently been rolling 60 foot rails to order, which has called out considerable discussion as to their superiority over the ordinary 30 foot rail. The arguments in their favor are that they cost no more per pound than the 30-foot, and may be made for less, while two drop ends are saved. This is an item of no small moment. How to use drop ends economically is one of the serious problems at Bessemer steel works. Two 30-foot rails, of course, give four drops, and a 60-foot but two, which at once takes out of the question 50 per cent. of the difficulty. With a view to this cheapening of production by reducing waste the above works were designed to make 60-foot rails.

The saving in their use by railroads is not so evident, but it would doubtless be found more economical to use the longer rail. The cost of laying them will be less, and the wear and tear of rolling stock as well as the rails themselves will be much lessened. A larger part of the wear and tear is due to the "hammering" caused by the shock in passing from one rail to another, and on a track with 60-foot rails the number of joints will be lessened one half.

Some of the 60-foot rails ordered have been for laying on bridges, on the supposition that reducing the number of joints will reduce the strain on the parts of the bridge.

What the effect of expansion upon a track laid with these longer rails will be has to be seen. Of course, with only half as many joints the distance between the rails allowed for expansion and contraction will have to be greater, but in arranging the track for hot and cold weather only half as many joints will have to be attended to.

IRON VESSELS.—The steamer *Great Britain* was one of the first made iron vessels, and among the earliest to ply regularly between New York and Liverpool. She has lately arrived at the latter port from Melbourne, Australia, thus completing her 36th trip round the world. She was designed by Brunel, and built at Bristol. Her dimensions are: length (extreme), 330 feet; breadth, 57 feet; depth, 32 feet; with engines of 500 nominal horse-power. Since 1852, independent of her employment in the Crimea during 1854 and 1855, she has sailed over 1,000,000 nautical miles, her last voyage out from Gravesend to Melbourne only occupying 54 days, and when recently surveyed, she was pronounced to be one of the strongest vessels in the mercantile marine.

ELECTRIC LIGHT FOR LOCOMOTIVES.—Experiments with the electric light as a head light for locomotives, have recently been made in Russia, on the railroad from Moscow to Kursk, with successful results. The apparatus consisted of a battery of 48 couples, which produced sufficient illumination to light up the truck for a distance of 1,500 to 1,800 feet ahead. Instead of a battery, however, we presume it will be found much more easy and satisfactory to use a magneto-electric machine driven by the engine itself.

Nor only is certain hardware of American make sold in Australia, but American tool steel also, and is spoken of with favor. English steel has long had that field to itself, and if we are to have our steel sent there by invitation of preference, won't Bull stamp and paw?

Propeller Screws in Casings.

Mr. Griffiths, whose experiments with H. M. S. *Brusier* have attracted much attention, has been making some further trials with models at the swimming bath of the Greenwich hospital schools. The results which he has obtained from these latter trials are somewhat remarkable. Taking two models, representing the type of the long narrow and the short broad ship, both of the same displacement, and being respectively five inches long by seven and a half inches beam, and three feet one and a half inches long by 14 inches beam, Mr. Griffiths showed, by towing them at the ends of a cross beam, that the resistance of the water on the long one was to that on the short one as three to five. On putting a pair of twin screws in the ordinary position at the stern of the long ship, and driving them for 60 seconds by means of a piece of clockwork machinery, the model was propelled through the space of 55 feet. The short vessel, however, with the screws in the same position, was only propelled, with the same machinery, through the space of 28 feet in 60 seconds; but when the screws were placed inside tunnel casings with lip orifices, the model was propelled through a space of 62 feet, being, as will be seen, greater than that traversed by the long model when propelled in the ordinary manner. It was also found that, even when the screws were placed in the ordinary position in the short model, but the tunnels left open in front of them, a better speed was obtained than when the tunnels were closed, though not so good as when the screws were actually in the casings. The *Engineer* states that these results were considered of so much value by a gentleman representing the Imperial Russian government, who was present at the trials, that, at his suggestion, Mr. Griffiths has undertaken to have a model of a circular iron-clad made, and to conduct some trials therewith as to the difference of speed to be obtained by his system over that now used in the *Popoffka*, the circular iron clad.

A DOMESTIC STEAM ENGINE.—M. Riser, of Paris, has patented a portable steam engine, adapted for all sorts of purposes—hand turning, watch-making, machine sewing, stamping, hand sewing, etc. The boiler of this machine consists of two concentric cylinders of iron plate, the inner lining containing a serpentine of sheet metal with a furnace beneath, while the space between the cylinders forms a steam chamber. A feed cistern surrounds the fire, so that the water heat is utilized in raising the temperature of the feed water. A spherical metal case incloses the safety valve and steam port. These engines are made in various sizes, from ½ to 2-horse power. One of this principle, having ½-horse power, was recently exhibited in the Maritime exhibition. The generator of that was 2 feet high and 14 inches in diameter, and by an ingenious disposition the serpentine presents a heating surface of nearly 9 feet square, so that steam can be raised for working in about 12 minutes after lighting the fire. The coke consumed in working this engine is said to cost only one-half penny per hour, and the engine has a capability of driving a sewing machine as well as a circular saw 15 inches in diameter.

NARROW GAUGE RAILROADS.—An enterprising Bostonian, who has practically given his life to the study of railroading, and who has examined nearly all the roads in this country and in Europe, has recently concluded a series of experiments in narrow gauge railroad building, the results of which, he holds, are destined to create a revolution in the construction of railroads. He claims to have demonstrated that a road with a gauge of 20 or 24 inches is all sufficient for railroad purposes, and that the practicability of introducing excessively narrow gauge routes in places where common railroads cannot be built at all, or could not be operated at all, is beyond dispute. He estimates that by his plan a road can be built and equipped with rolling stock for \$5,000 a mile, and by winding round hills can be made to reach even to the highest settlements in the mountains. As connecting links from isolated towns to lines of existing railways they will prove of great benefit; and in the West, especially, where towns are widely separated, a railroad that could be built and equipped so cheaply could not fail to be universally adopted.

A NEW MODE OF GAS MANUFACTURE.—The *Gas Light Journal* records the following: An invention has just been made by Mr. John Mather, of Gateshead, by which atmospheric air rushing through a jet produces a vacuum in a small chamber or generator, into which also opens a jet from a vertical tube descending into a cistern containing a carboniferous fluid. This vacuum causes the fluid to ascend the tube, and to issue from the jet in a spray, which combines with the air rushing by. This combination is carried along a tube that passes through a furnace or oven, and finally conveyed in a gaseous state to the hydraulic main, and thence to store tanks.

A NEW LOCOMOTIVE.—A new locomotive has been recently completed in Philadelphia, under the direction of Mr. Weston, of Manchester, England, for the Pennsylvania railroad. It is claimed to possess greater power and to run at less expense than any other engine, as it utilizes both smoke and steam, and that it will draw a heavily-loaded train of 100 cars and can be stopped within its own length. The cab is on top of the boiler and the smoke stack is the size of a common stovepipe.

The usual dividends have been announced for the month, and a new one also, that of the Empire mine of Howland Flat, Sierra county, of \$5 per share. The dividends of mining companies, last month, amounted to \$1,368,600. The assessments delinquent this month aggregate an unusual sum, \$1,026,700; of this \$818,800 is on Nevada mines, \$97,900 on California, \$80,000 on Idaho and \$30,000 on Utah mines. The number of mining assessments delinquent in March, 1875, was 40, aggregating \$1,197,000, against 25 for the same month in 1874, aggregating \$748,600.

As will be seen by our list of new incorporations, the papers of the incorporation of two companies were filed last Saturday—the Chollar and the Potosi, each company to have 112,000 shares. These are the corporations which are to absorb the old Chollar-Potosi company, and the division will be four shares in each of the new incorporations to one of the old. This will give 224,000 shares to the 28,000 which comprises the present capital stock of the

The Yellow Jacket company, at the meeting held in Gold Hill on Wednesday, decided to increase the capital stock from \$2,400,000 to \$12,000,000, divided into 120,000 shares. It is not yet known when the new shares will be issued.

The collapse in prices of mining stocks over last week's sales shows no improvement, and the "bears" are still masters of the situation. These week fluctuations have been quite unimportant, although the volume of business done is quite large. Those who thought the break was to be only a temporary one found themselves mistaken, and the "shorts" on the rising market, what few there were, must be badly off.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

THE AMADOR CANAL.—*Amador Ledger*, March 4: The company is making several improvements on the canal. The dunes are being raised 12 inches so as to enable the ditch to carry more water than heretofore. When this is accomplished the canal will carry about 3,000 inches of water. Extensive improvements are being made at the bulkhead. Altogether these improvements will involve an outlay of many thousands of dollars.

BUTTE.

WATER DITCH.—*Butte Record*, March 11: We learn from H. F. Yokum, Esq., formerly of Dayton, Ohio, who was engaged in constructing a ditch to carry water to the Butte Creek mines, that they will be able to turn the water on to the upper diggings in about 20 days. The ditch will be extended some five miles further down, so as to cover most of the bank diggings along Butte creek.

BUTTE CREEK MINES.—*Dr. Brotherton* was in from Centerville on Wednesday, and reported the miners doing but little during the late rain, as it was too severe for them to work. Most of the canons were running with water. He brought in but little dust.

CALAVERAS.

GWIN MINE.—*Calaveras Chronicle*, March 4: We have intelligence of an exceedingly flattering character from the Gwin mine. Developments in the 1100-ft level are surpassing the most sanguine expectations. The ledge, at a distance of about 100 feet from the shaft, has widened out to four feet and shows the richest rock yet discovered in the mine. The first and second stopes are already opened and others will be got in readiness as fast as practicable. The batteries are in motion and operations are being vigorously pushed, both to mining and milling. Present indications are all favorable that the 1100-ft level will yield more money than any of those above it did. At no period has the Gwin mine had so promising a future before it as it has to-day.

GLENCROCK DISTRICT.—In spite of the bad weather, considerable quartz mining is being done in Glencrook district. The upraise in the San Bruno is progressing rapidly and will reach the surface in a few days. This contractor, Mr. Boughton, is pushing things. Good rock is being taken from the Hadlock mine at the depth of about 70 feet. A large quantity of first grade ore is in the dumps of the Albers mine. It will be crushed as soon as work can be got to run the mill. An accident occurred to the machinery on the Grasshopper mine last Tuesday, but damages have been repaired and the pumps were started again Thursday. Quartz mining operations will be very brisk in Glencrook district when spring opens.

INYO.

A NEW TRAMWAY.—*Inyo Independent*, March 4: Col. Stearns, of Cottonwood, called on us a few days since, having just returned from a business visit to San Francisco. During that visit he received the assurance of all needed capital with which to build and equip a solid tramway from the lake to Darwin. It is a grand enterprise, perfectly feasible and by no means costly, taking into consideration the Colonel's Cottonwood mine and saw mill, by means of which he can obtain the required timber at a nominal cost, copper actively speaking. Such a tramway, even now, would be put to near its capacity right from the start, in transporting ore, coal, timber and other freight to and from the lake. It is likely, however, that work upon it will be deferred till some of the principal mines, both in Darwin and Lee districts, which later lie near the line nearest Darwin, 16 miles distant, are opened. The project is a grand one, and will create an extensive business of itself, in addition to what it will do for the hack freight of milling ore which the New Coso company are preparing to send to a contemplated mill at the lake for reduction, the most of the ores from their mines being of that class and not of a character to require smelting, a circumstance, and the only one, that has hitherto retarded the progress of the New Coso company's operations. They have some of the richest and best mines of that class yet opened in Darwin, but the ores are "dry" and unfit for smelting, except by close sorting or admixture with those from mines belonging to other parties. Their furnace at Darwin, however, will be kept running with such ores as are required for the district, and the product will be sent to the lake. Here, in brief, we have an outline of a very important and promising enterprise, and all quite certain to be fairly under way if not wholly completed in less than 12 months from date. The natural conditions for the consummation of each and all of these projects could not be better if they had been planned on the spot.

ROCK SPRINGS DISTRICT.—*Cor. Oso Mining News*, March 11: Since the Inyo mining company made the purchase of the Nossano company's mines, the camp has changed its appearance, and, instead of being the resort of a few prospectors, is shaping itself into a busy mining camp. A town site has already been laid out, a station erected for the accommodation of those visiting the district, and the district has taken on a new and improved air, and work on the Garabaldi and North Star mines commenced. The district is fast filling up with strangers, in search of mines and labor. Among the new arrivals are Messrs. Gashweller and Maynone. Mr. Irwin, superintendent of the Inyo mining company, has established his headquarters at the North Star mine, and is only awaiting the arrival of the Nadeau's teams, with a full supply of mining tools, etc., to commence active operations on their several mines. Their prospects are indeed flattering, and it is the prediction of all who have seen the property that they have purchased, that theirs will prove the most prosperous of any mining enterprise on this side of the Sierras. They secured several well defined ledges, showing, probably, the richest average crop of silver ore yet found in the rich district of Virginia City, and much surprise is often expressed that they could have purchased it at so low a figure. There are other valuable ledges in the district, and ample room for other companies to invest; and, as spring advances, we will, no doubt, have quite an influx of capital, as there are several parties of prospectors who have been out at times of late springs, and more, and who hold ledges of considerable merit, from whom capitalists can purchase a set, or even several sets or groups of ledges, numbering from three to 10 or 12, and which now lie undeveloped, together with mill sites with sufficient water for milling their ores. The records show that about 165 ledges have been located in the past year, and for the year 1875. Dr. Goerge and E. M. Bentley have been working for the last three months on several of their ledges, and I am told have developed some valuable mines. They came here about a year ago, and, after making several locations, returned to their homes at Visalia, and having no success in the purchase of the mines here, returned with supplies for working their ledges, and merit their success, for it is such men that give a camp its stability.

DARWIN DISTRICT.—In the Defiance mine the drift from the bottom of the south wing hanging wall is now in a little over 100 feet, in ore all the way to the top of the drift. The drift is a solid body of galena. About 30 feet from the bottom of this winze a cross-cut has been run some 30 feet, through a body of galena and carbonate ore, the hanging or west wall not yet having been reached, and consequently it is impossible at this time to give the width of the vein. The ore taken from the drift will yield from \$100 per ton. The Defiance furnace has been running very successfully since our last report, with the exception of about 12 hours, during which time she was compelled to shut down for the purpose of repairing the water jacket, which had sprung a leak. Mr. Frank P. starts below to-day for the purpose of purchasing and settling on the construction of another furnace for this company. The shipments of bullion since our last issue include 930 bars of 80 pounds each; remaining on hand, 140 bars.

LEE DISTRICT.—On the recent visit of Mr. Taylor, the new superintendent of the Emigrant mining company, we were shown some very fine specimens of ore and quartz veins. It is mostly superfluous ore of a superior quality, and will, according to the estimation of Mr. Taylor, between \$700 and \$800 in silver. The machinery for the mill of the company arrived here some days ago, but cannot be transported any further than the mill, about two miles from the mill site, at present, on account of the prevailing snow. It will take about a month before the company can begin operations and have everything in running order.

NAPA.

CALISTOGA CONSOLIDATED.—*Cor. Napa Reporter*, Mar. 11: The weather this week has prevented me from visiting the Calistoga Consolidated quicksilver mine as I had intended. From Mr. R. K. Brown, the superintendent, I got the following facts. The mine comprises five claims, all of which have been worked more or less. The amount of tunneling is about 300 feet, and shafting 75 feet. The shaft we are now working is down 60 feet, with good ore all the way, and improving as we go down. The ore seen at the bottom of this shaft (No. 2) is about two feet in width, and growing wider as we go down. The water in the shaft is very pure. Work has been much retarded by the stormy weather, but we shall take hold in earnest, as soon as the weather permits. There is an abundance of wood and water at the mine, and an excellent site for a furnace. The mine is owned by Messrs. Erwin, Thatcher, Brown, Stacey and others, and has an excellent prospect. It is situated about 10 miles from the county road to St. Helena, and no roads will have to be constructed, as old wood road having been repaired to enable teams to reach the mine, which is about two miles south-easterly from here.

NEVADA.

THE GOLD YIELD.—*Nevada Transcript*, Mar. 9: It has been with more trouble than at first anticipated, that we have been enabled to get the following facts and figures of the amount of bullion taken out and shipped from that portion of Nevada county known as the Ridge. This includes only the bullion shipped through the express facilities of that section, with the approximate amounts that were sold to the Bank of Nevada County, and taken by private hands for the past year, 1875, from the 1st of January to and including the 31st of December of that year. From the banking house of Marks & Co., Moore's Flat, \$398,000 in round numbers. This large sum was all produced at that point and Relief Hill, including the several places in the vicinity. From Wells, Blooming, and the Bank of Nevada County, gravel mining company's mine, the sum of \$8,000 will here say this product from the top ground, as the company have not reached the bedrock in the channel of their mine at this writing by probably 20 feet or more. They have struck large boulders on the easterly rim, indicating conclusively that the channel of the ancient river bed still remains further to the north-west. The mine is situated on a bench, and the nearer they approach the bottom. This is without doubt one of the richest hydraulic mines in the county, or will be when opened in the channel and on the bedrock. At North San Juan the amount shipped reached \$322,557, a very large portion of which was produced from the top ground of the American company, at Seaboard, Nevada. The sum of \$178,000, all of which was shipped to the Bank of Nevada County, except a few thousand dollars shipped by W. Villard & Co.'s few months' run with a short water season. There was probably sold to the Bank of Nevada County, from Hustler & Son's mine, and Hawley Brothers' mine, with the amount taken from Humburg creek, by China-men, about \$30,000 in round numbers. These evidently represent a large amount of bullion, which have been carried off by private hands, and small parcels which should be estimated at not less than \$20,000. This gives the total yield from that portion of the county, of \$1,454,317. The reader must bear in mind that this large amount was produced in the year of one of the shortest water seasons known since '49. It would be safe to say that, after the several tunnels that are being run are completed and in good running order, that the above figures can be doubled yearly for the next quarter of a century.

PLACER.

BEAR RIVER MINING NEWS.—*Cor. Dutch Flat Forum*, March 9: The first claim you come to if you are Ucle Ritchie's, which at the present time is the banner claim of the river. He is now working on the upper portion of his claim with varied success, and the way he is situated, to some disadvantage, but every one in a while comes a nugget day. He has got some splendid rock to work, which I believe to be very good. The first claim you come to if you are Ucle Ritchie's, which at the present time is the banner claim of the river. THE ENGINEER.

Modern Engineering.

In our issue of February 25th we made some allusion to the Genesis of architecture and engineering, and passed in brief review some of the most noted engineering works of the ancients. Allusion was also made to the fact that but little was known of the engineering methods and mechanical appliances employed in those early days. Our present purpose is to give a brief resume of modern engineering.

Engineering progress in Europe, and indeed throughout the world, was stopped with the fall of the Roman empire. The barbarous hordes which passed over that continent from Western and Central Asia had no need of roads or bridges or temples. Their mission was one of destruction, and their presence hung like a pall of darkness over the world from the 4th to near the 10th century.

Modern engineering may said to date from the last named period, at which time a great building era commenced in Southern Europe and continued for about 300 years, during which time the great ecclesiastical structures which characterized that period were erected or commenced. While this work, remarkable chiefly for artistic excellence and originality and boldness of design was in progress, many other more strictly engineering works and works of utility were also undertaken, in the way of canals, and for the improvement of harbors and rivers. Canal locks, for transferring vessels from one level to another were first introduced in 1481. Their originator, Leonardo da Vinci, if he had left no more skillful or attractive work, would for this alone be entitled to the homage of the civilized world. But the great hydraulic works of Holland, constructed for driving back the sea and reclaiming vast tracts of valuable land, commenced as early as the 12th century, formed, with their accompanying machines for lifting water for drainage, the most formidable engineering works extant up to the time of the invention of the steam engine. The designers of those works thus became the leading engineers of the world, for the time being. The English were for many years—quite up to the time of Cromwell—dependent upon them for nearly all the engineering skill employed in their hydraulic operations.

The introduction of the steam engine in 17— and the consequent rapid extension of manufacturing industry opened also new and enlarged fields for the engineer. Previous to this time the ablest mathematicians, philosophers and men of science generally were called upon to advise and superintend great works of engineering. Archimedes was employed to devise works to defend his native city from its besiegers, and nobly fell while thus engaged. Some of the greatest philosophers during the era of the revival of letters, were called upon to take charge of great national works of improvement; among them may be honorably mentioned Torricelli, a pupil of Galileo. But, with the new impulse given to industry by the introduction of steam as an aid to mechanical labor, engineering took such a wide range and called for so much and such varied talent, study and experience, as to necessarily make it a school of itself.

It was at this time, too, that the profession took its modern title—engineer—from the term engine. The name was first applied, we believe, by the French—*ingenieur*, and was originally confined exclusively to one who had charge of a steam engine; but soon afterward received a more general acceptance, and from the Latin *ingenium*, a contriver, was applied to all who devised mechanical means to any desired end.

It is the province of the engineer to substitute for the slow and laborious toil of the hands and fingers some ingenious mechanical contrivance by which the same work can be done quicker and cheaper than by hand. The modern engineer is a great economizer, and a great civilizer as well. One pair of hands, through his ingenuity, is enabled to do the work of hundreds or thousands of unaided hands. Nearly all the artificial comforts of modern life are due to the skill and inventive genius of the engineer. His position, too, is often one of great responsibility. On the accuracy of his calculations in regard to the strength, position and fitting of materials depends the lives of the throngs who go out upon the deep in ships, and all who trust themselves to the awing bridge or the rushing car.

Again, it is the duty and privilege of the engineer to find employment for idle money, to devise ways for developing the resources of a State or nation, and means for the protection of that nation from the hostile attacks of its enemies. In carrying out this work he has revolutionized the art of war, both on sea and land, in the construction of iron-clad ships, iron roads and superior ordnance.

The engineer is called upon now to protect us from the invasions of water upon our valleys and plains, and again to lead that same element, for irrigating purposes, by convenient ways, over our farms and vineyards, all through those same valleys and plains. Again we look to him to protect our cities from disease and death, by bringing thither the life giving waters from great distances and through seemingly impossible ways. Then again we need his services to devise ways and means by which we may penetrate, for thousands of feet, into the

deep, dark recesses of the earth, to bring up therefrom the shining metals which give life and energy to commerce and industry. In short, it is the engineer's province to pioneer the way for all industrial progress; to look after the national weal and health and life, and to devise ways and means to improve the mutual economy of the world at large. Such are the varied responsibilities which have devolved upon this profession by the new conditions of society and industry which have grown out of the invention of the steam engine.

The introduction of the steam engine, through the ingenuity and method of the engineer, has given us the steamship and the railroad, which science has supplemented in the electric telegraph, with each of which, their history and accomplishments, the world is familiar. The two former have still further greatly enlarged the sphere of the engineer. Indeed, without him the railroads would still have been but little in advance of the original tramway, while the steamboat, to the present day, would have merely threaded its way through our rivers or hugged along the coast, unequal to the dangers of the open sea. Fifty years have scarcely passed since science scouted at the idea of a railroad car snipersing the stage coach, while it pronounced the project of crossing the Atlantic in a steamship the very height of folly! Now the railroad, almost our only means of traveling on land, spans continents and unites nations; while the smoke of our steamships darkens all the great ocean highways.

In England the Eddystone lighthouse, the Menai straits bridge, the Plymouth breakwater, the Liverpool docks, the Albert viaduct across the Tamor above Plymouth, and the Thames tunnel in London are all marvels of modern engineering. It was at the construction of the Albert viaduct that the distinguished engineer, Bunnel, first introduced the principle of excavating foundations for bridge piers by the use of an iron cylinder, within which the men worked under an atmospheric pressure varied according to the depth, sufficient to keep out the water by that pressure. The placing of the two main spans of this viaduct was also one of the greatest engineering feats ever accomplished. The central pier upon which they rested was 190 feet in height from the bottom of the foundation, viz: 20 feet from hard gravel to top of the mud in the bottom of the river; 70 feet of water above and 100 feet from water surface to the bridge to allow of the free passage underneath of the largest ships which were accustomed to pass up that estuary. To place these huge spans, (which consisted of tubes of boiler plate, arched in form, each 470 feet long, 17 in width and 12 in height, weighing 1,200 tons) they were floated out on iron pontoons, raised by hydraulic rams three feet every other day, as the main work of the pier progressed above the water until it reached its topmost course.

The engineering works in the United States are chiefly exhibited in our long and difficult lines of railroads, in our canals, fortifications, breakwaters and bridges. In the first and last we are in no sense inferior to any other country on the globe. The St. Louis bridge, lately completed, is a marvel of engineering; while the bridge now in course of construction between New York City and Brooklyn, is, perhaps, the grandest piece of engineering work ever devised.

With regard to the future of engineering—who will dare to predict? A distinguished Englishman recently said: "Engineering depends largely on experience; nevertheless in future times, whenever difficulties shall arise, or works have to be accomplished for which there is no precedent, he who has to perform the duty may step forth from any of the walks of life, as engineers have not infrequently heretofore done. The marvelous progress of the last two generations should make every one cautious of predicting the future. Of engineering works, however, it may be said that their practicability or impracticability is often determined by other elements than the inherent difficulty in the works themselves. Greater works than anything yet achieved remain to be accomplished—not, perhaps, yet awhile. Society may not yet require them; the world could not at present afford to pay for them."

LIGHTHOUSE BUILDING UNDER DIFFICULTIES.—A celebrated French lighthouse is that of Eaux-de-Brehat, a recent erection, based upon a huge and treacherous porphyry rock, for ages a terror of every seaman who approached the Brittany coast. Its architect had to encounter every species of obstacles during his work, but, above all, incessant races and eddies of the sea among the neighboring sandbanks. The foundations had to be sought for far beneath low water; an artificial port had to be created; the necessary stone work was hewn and shaped on the island of Brehat, seven miles distant. Even when the foundation wall had appeared above the water the lower walls of the lower story were submerged twice a day, leaving heavy deposits of marine plants, shells and seaweed. The workmen lived in huts upon a reef, to which they retired when the tide rose; and then they pushed on their labors, quarrying and squaring at one time, arranging and fixing at another. There was a masonry almost without mortar. The blocks were grooved and literally dovetailed together, the course being connected, as it were, by cogs, so that every part relied upon every other, the result being, as nearly as possible, an absolute cohesion. In spite of this happy issue the reporting architects would not recommend similar experiments in the future.

Street Railroad Locomotion.

An experiment which was made recently just outside the walls of Paris promises to effect far greater results than was anticipated, even if it does not produce a sort of revolution in the ordinary means of locomotion. The object was one which has been over and over again attempted to attain—that is to say, the substitution of steam for horse power on tramways. But the innumerable inventions by the aid of which it has already been attempted to solve the problem have all been open to fatal objections on one score or the another. Either the machines constructed have been too slow, or too cumbersome, or too noisy, or too expensive, or even too ugly; for the horse, which next to mankind has hitherto, at least, had the best right to the road, will not endure a competitor whose hideousness of aspect exceeds a certain reasonable limit.

But the tram car in which a French engineer has now solved the difficulty appears to be free from almost, if not quite, all these manifold defects. From its elegant white chimney issues a faint white vapor, whose delicate appearance is rather pleasing than repulsive. The brake power is capable of prompt and efficient application, and the engine is packed into a case which is neither extravagantly large nor intolerably ugly. The whole cost of feeding and working it is estimated at only 20 francs a day, whereas the total expense of maintaining a pair of horses working an equal number of hours amounts to a great deal more.

But the grand triumph is, perhaps, the speed with which the steam tram car travels. Between the Porte de Chatillon and St. Germain des Pres its mean pace—up and down a slight incline—was just 300 metres to the minute, that is to say, a rate of at least 10 miles an hour with a full load of passengers. The experiment was witnessed by a number of public dignitaries, including the director of the works, and it is obvious that a step has been made towards utilizing steam power upon roads which may lead to the most serious results in a commercial, economical, and, more especially, an agricultural point of view.

The following, from *L'Illustration Universelle* (Paris), doubtless describes the machine alluded to: "This machine, based upon the elasticity of compressed air, presents in its make-up the appearance of an ordinary street car. In front is placed the platform, upon which the conductor takes his place. Under the frame work, supporting the box, are placed sheet-iron cylinders, fixed transversely, proved to bear a pressure of 30 atmospheres, into which the air is forced by a pump moved by steam power, although the air is stowed away at the enormous pressure of 30 atmospheres, that it may occupy the smallest possible space, and consequently be more portable, the compressed air need not be used at a greater pressure than of three, four or five atmospheres, according to the loads to be carried, or the obstacles on the road. It then became necessary to invent a particular system of expansion, which should not allow to pass into the motor-mechanism more than the exact quantity of air required to produce the necessary effect. This mechanism is placed on the front platform, is operated by the hand by means of a wheel, by the conductor, who can, by observing the pressure on two indicators, regulate the flow of air into the cylinders, and consequently increase or retard the rate of speed of the car. But it is known that air is heated when compressed, and that it cools, more or less, according to its expansion. The inventor of this car has guarded against this danger by making the air run into a reservoir of water heated to 180 deg. It is thus passed into the motor-cylinder under the car, heated and covered with moisture."

The advantage of some such system of street cars, moving without smoke or any of the noise peculiar to steam machines, and presenting no danger from fire explosion, must be obvious to all. Whenever such a machine is found that will combine the above conditions, it will soon come into general use and be considered a public blessing. It is further said of this Paris machine that it is capable of doing the work of 200 horses for \$10 per diem of outlay.

ENGINEERING DREAMS BEING REALIZED.—George, when in his 78th year, said there were three things he desired to see: A canal connecting the Gulf of Mexico with the Pacific ocean, another connecting the Rhine and Danube and lastly, the English in possession of a Suez canal. "I should like to see these great things," said he, "and for them it would be worth while to endure another 50 years." The English came into possession of a Suez canal just within the half century.

The tunnel, as projected under the English channel, will be 16 miles long and 250 feet below the bed of the sea.

A few days ago Mr. Keyes, the superintendent of the K. K. Consolidated mine, says the Eureka Sentinel, discovered in the fifth level of that mine several skeletons of kangaroo or wood rats. The rodents, upon the approach of death, of which they have an instinctive knowledge, seek some dark place, oftentimes, as in this instance, finding their way into apertures in the rock or earth hundreds of feet below the surface. The discovery of these remains prove conclusively the connection of the oases with the outer world, and is a strong argument in favor of the theory that the water in the mine comes from the surface.

Silver Lead Ores.

Smelting and Base Bullion Production of California.

A correspondent of the *Coso Mining News* writes to that paper as follows: The discovery on this coast of large deposits of argentiferous galena, and other ores requiring treatment by the process of smelting, imparts to this class of deposits and method of reduction particular interest at the present time. As the locality in which the earliest of these discoveries were made, and in which the mode of treatment was first introduced, and where it has since reached the most satisfactory results, the Cerro Gordo district, Inyo county, has special claims on public attention; having received in that locality their first practical lessons in the metallurgy of this class of ores, our people will naturally incline to adopt the plans there employed, and look that way for further information on the subject. With a view to applying a few of the more prominent facts connected with the history of that district, and some other data pertinent to the matter in hand, we yield for that purpose such space as can now be spared.

Locality and General Features.

Cerro Gordo, meaning in the Spanish the "Hill of Riches," lies on the westerly slope of the Coso mountains, a high range situated some twenty miles east of the Sierra Nevada, from which it is separated by Owen's river valley. This district lies at an altitude of between 6,000 and 7,000 feet, being a thousand feet or more above the valley adjacent. These mountains are covered with a good soil, which produces a rich pasturage of bunch grass and a scattered growth of timber, consisting of pinon, cedar and mahogany. These trees, although of insufficient size to make good lumber, are unsurpassed for fuel, the pinon and mahogany making also the best of charcoal. Lumber for this region is procured from the Sierra Nevada on the opposite side of Owen's valley, the timber on these mountains being large and abundant. Flowing through the canons along the western face of the Coso range are many small streams, alike serviceable for irrigation and mining purposes. Though so elevated, but little snow ever falls in the Cerro Gordo district, nor is the cold at any time extreme, though the summers are warm. The water is good and the climate invigorating and healthy. Owen's river valley contains much fine agricultural and grazing land, all the products of the farm and dairy being supplied to the neighboring mining camps at moderate prices.

The Discovery of These Mines

Was made by a company of Mexicans prospecting the foothills here 12 or 13 years ago. Their acquaintance with this class of ore in their native country enabled these people to appreciate its value, wherefore they stopped, put up rude furnaces, and commenced running out the metal, the most of them having remained here since, working in a small and inefficient way. About eight years ago, two unskilled but industrious and energetic men, Belshaw and Beaudry, came into the district, and being satisfied of its wealth they too concluded to remain and go to work. Like their predecessors their earlier efforts were confined to a small scale. But they were not the men to be contented with this. They commenced experimenting on the ores, and overcoming such minor difficulties as presented themselves, gradually multiplied and enlarged their furnaces, acquired additional properties, worked hard, and finally so extended their operations that they now count their annual product of bullion by the thousands of tons. Their principal mine, and that from which the most of the ore for running their furnaces have been taken, is the Union, they being owners also of many other claims. Several other companies are carrying on a thrifty business here, opening up their mines, smelting the ores, erecting new furnaces, and otherwise extending their improvements, while others again are driving deep explorations and work-tunnels designed to develop and drain an entire series of lodes to a great depth. Among the more active and prosperous organizations operating here are those of the Potosi mining and smelting company, the Swansea company, and the Owen's Lake silver and lead company, all the owners of valuable franchises, properties and improvements, the last two having also smelting furnaces in operation. To aggregate a little, there has during the past seven years been invested in this district, including only outlay of leading companies, something like \$130,000. The production of base bullion meantime has amounted to, say, 25,000 tons, worth \$5,000,000, and from which there has resulted a net profit of \$2,500,000. Two years ago the lead, or base bullion so called, had accumulated here to the extent of 2,000,000 pounds, compelling the principal furnace men to engage the services of no less than 80 12-mule teams to haul it to Los Angeles—the return freight teams, though large and numerous, being unable to keep the stock reduced to a reasonable limit. It must be understood that the \$130,000 referred to did not consist of money borrowed or brought in from abroad; it was the fruit of current net earnings, for this has been not only a self-made, but a self-sustaining district from the first.

What promises to accomplish more for this district than any or perhaps all other enterprises combined is the great

Exploring and Working Tunnel

of the Potosi mining and smelting company, now in course of construction. Before proceeding to describe the features and objects of

(Continued on Page 186.)

USEFUL INFORMATION.

How to Get Rid of Household Pests.

I have not seen a bedbug or flea in my house for many years. If an army of them were to be brought in, mercury would speedily exterminate them; but I think cleanliness the best and perhaps the only preventive. The common house fly I do not molest, believing that it more than compensates for its trouble by clearing the atmosphere of effluvia and the animalcules which always arise from the putrefaction of decaying substances during warm weather.

So also with the birds, which are quite numerous here during the summer. Instead of shooting them or setting up scarecrows to frighten them away, I throw out every possible inducement for them to build in my fruit trees. The birds capture a large share of the insects in the larva state, and thus the millers are prevented from depositing eggs for future worms. As to the loss of fruit by the birds, this latter are always sure to be on hand in force in the season of ripe fruit, whether they come early to take the worms or not.

For the residue of insects that infest my vegetable garden, I find that the laboratory of the chemist furnishes materials fatal to them all, among which white bellerose and cayenne pepper are of the most ability. The bug or worm which cannot find vegetation unflavored with these articles will seek its breakfast elsewhere and leave a garden unmolested.

A few drops of carbonic acid in a pint of water will clean house plants from lice in a very short time. If mosquitos or other blood-suckers infest our sleeping rooms at night, we uncork a bottle of pennyroyal, and these insects leave in great haste, nor will they return so long as the air in the room is loaded with the fumes of that aromatic herb. If rats enter the cellar, a little powdered potash thrown into their holes, or mixed with meal and scattered in their runways, never fails to drive them away.

Cayenne pepper will keep the buttry and storeroom free from ants and cockroaches. If a mouse makes an entrance into any part of your dwellings, saturate a rag with cayenne in solution and stuff it into a hole, which can be repaired with either wood or mortar. No rat or mouse will eat that rag for the purpose of opening communication with the depot of supplies.—*Scientific American*.

A Hint to Young Mechanics.

Two things are uppermost in almost every industrious young man's mind: the desire to make and save money, and to be established in business for himself. Now, as an encouragement to persevere in that industry, also in faithfulness, close attention to business, and also in improvement of the mind, we suggest that a few dollars placed at interest will grow in amount wonderfully fast, if the interest is also invested and a few dollars regularly added to it. The evenings usually spent in idle ways, if devoted to scientific, practical books and papers, will in a few years make a young man educated and prepare him for directing an establishment of his own. Remember it is the most skilful, artistic and finished workman that rises above his fellows. When you have mastered your trade and find your mind stored with useful hints and thoroughly scientific knowledge, then turn to a partnership or part interest in business with your employers. Your standing and the little capital saved will help you wonderfully. If each a part interest is not practicable, select a collaborator and commence in a one-story, one-roomed office, with a particular specialty of which you are masters. Push to completion in perfect workmanship each small order as you can persuade the public to extend you. Remember that personal application, integrity and industry will, in a few years, bring their reward. They always have, and they always will.—*Mechanical Journal*.

ORIGIN OF RAILROAD GAUGES.—DIFFERENT VARIATIONS.—An eminent engineer states that the origin of railroad gauges occurred as follows: George Stephenson adopted the four feet nine inches gauge for the reason that it was used in all the horse vehicles in England; and when the parts of the first locomotive were ready, and were put together, owing to some unexplained cause it proved to be only four feet eight and one-half inches in gauge, and lo! the whole railway world have followed the pattern thus produced, and hence our present standard. A correspondent of the *Scientific American* writes that journal as follows: "My book of reference says that the gauge was originally five feet, and the flange of the wheel was on the outside. That not working satisfactorily, the flange was changed to the inside, which makes the measurement four feet eight and one-half inches." Another correspondent of the same journal says: "The first railroads were constructed for coal traffic, and were of the same gauge as the colliery tramways, four feet eight and one-half inches; and the latter are so old that no one can now tell why this width was chosen."

SPOKEN LANGUAGES.—Dr. Butler, of the Methodist mission in Mexico, draws attention to the fact that the Spanish language stands third in the list of European tongues, being spoken by more people than any others except the English and German. Of the 50,000,000 for whom the Spanish is the mother tongue, over 29,000,000 live on this continent.

Things To Be Remembered.

A cotemporary furnishes the following as important matters to be kept in mind by all farmers. There are many others than farmers who will do well to bear more constantly in mind the same class of facts. We quote:

One of the most important things in any business is the preservation of what has already been acquired, whether of one character or another. For instance, there are the machinery and implements essential to farm work, and these must be taken care of. French experimenters hold that the friction of wooden surfaces rubbing on each other amounts to from one-quarter to one-half of the force employed. The friction of metal on wood is less; and that of metal on metal is from one-fifth to one-seventh. Lard, applied to wood surfaces, reduces the friction from 1-10th to 1-25th of the power required to move the surfaces, and on metal surfaces the friction was reduced one-half. These facts show the importance of lubricating machinery regularly—a fact that every farmer knows perfectly. Yet it is often neglected, and if the losses sustained by the average farmer in 10 or 20 years from this neglect could be actually computed every one would be astonished at the large amount.

It has often been observed that a common error in lubricating machinery is, that too much oil is applied. Whatever excess of oil is applied is necessarily a total loss, as surfaces in rubbing can use only so much oil; and though the loss at each application may be very small, in the course of a quarter of a century it will amount to a considerable sum. There is, too, a knowledge necessary even to the simple act of lubricating a wagon. The axle should be carefully cleaned by wiping, and the boxes require the same preparation for the reception of fresh oil, though good wagoners only attend to this last. We have seen, in more than one instance, a want of knowledge to clean the boxes, yet nothing is more simple. A cloth twisted around the axle to make it fit the hole through the hub, and the wheel made to revolve a few times, will effectually clean the boxes, so that the fresh oil will touch every point of the friction-surfaces in the hub. Machinery properly cared for will last double the time that it will if not properly cared for. This is a fact well attested.

For kitchen and pantry floors there is nothing better than a coat of hard paint. The cracks should be filled with putty before it is applied, and the paint allowed to dry at least two weeks before using. Then it is easily kept clean by washing (not scrubbing) with milk and water; soap should never be allowed to touch it. "Red lead and yellow ochre I prefer for coloring; the former makes a hard paint that wears well."

A LARGE lake has been discovered about 40 miles west of Laramie, W. T., in the bottom of which is a thick layer of sulphate of magnesia or epsom salts in almost a pure state.

A TRIPLE RAILWAY.—A third set of rails is to be laid on the Erie road from Elmira to Buffalo, to allow cars of the Lehigh Valley to be run through.

BLAST FURNACES IN GREAT BRITAIN.—At the close of 1875 there were 993 blast furnaces in Great Britain, but only 582 of the number were in blast.

GOOD HEALTH.

The Skin.

We desire to present a few brief and practical remarks upon this subject, without indulging in abstruse technicalities.

If as much, there is no structure of the physical body more widely distributed than the skin. It not only covers the external surfaces of the form, but reflects inwardly at every orifice, and, creeping into every cavity, lines the whole internal physique. What are commonly known as membranes may, with equal scientific propriety, be recognized as forma and modifications of skin.

The skin is best known as endowed with secretory functions; therefore, we shall confine our present brief statement to matters illustrating the natural law of secretion. Everywhere the skin sustains an adaptation to pouring forth some form of products for a wise and specific end. On the outer surface of the body it exudes perspiration, an oil for lubricating, and various effete matters from the armpits, toe-angles, etc.; in the nasal passages, throat and lungs, mucus; in the stomach, gastric juice; in the liver, bile; in the kidneys, urine; in various other localities, cardiac fluid, synovial fluid, prefrontal fluid, etc.

Whoever regards his body wisely will consider the importance of maintaining a proper activity of all the dermal functions. Especially is this true in view of the reciprocal relations certain of these functions bear to each other. To illustrate, if the functions of the external skin are unduly suspended, the internal skin will try to make up the deficiency by overwork. The same is true in a reverse contemplation. This explains why "closing the pores of the skin" will be frequently followed by an increased discharge of mucus from the bowels, or diarrhoea, as well as the same from the cavities of the head and fauces, or catarrh, and a great many similar compensating effects are accounted for in like manner. Last summer

we came in contact with a stranger, whose every outward aspect was indicative of the most scrupulous cleanliness and tidiness. Yet this very presence of the individual revealed a most intolerable stench. We doubt if the person most interested in it was aware of it. It proceeded from an undue secretion of the glands of the armpits. We have not a particle of doubt that the circumstances were owing to some other defective secretion in this way sought to be compensated.

Cases like the one we have related are very frequent and often exhibit more extended effects. The outer skin often secretes or perspires too much, because the inner skin secretes too little. In such a case, bathing and washing will accomplish but little in the way of relief. One may thus remove a quantity of detergent matter, only to have more supplied in its place. However, persons afflicted in this way will be less liable to direct injury from bathing than those in whom the predominance of force is exerted inwardly upon the mucous membranes, inciting most likely some form of chronic catarrh. Such are shivering and cold, and look with horror upon the face of water. If they persist in bathing they are liable to serious injury unless they use water only of an agreeable temperature, avoiding drafts of air both during and after the process. When experience shows weakness inclined to follow bathing, it should be practiced with great care, followed by a season of sassa and repose.

As a rule bathing is good for everybody. Excepting persons engaged in dirty employments, once a week is sufficient for those sustaining a healthy balance of secretory functions. Nor need it then be so thoroughly detergent as many imagine. A towel or sponge saturated with soapy or slightly alkaline water will soon do all that is required, unless one hates for pleasure. Friction of the dry towel or band, the air and the attendant muscular exercise are highly beneficial; weakly, or catarrhal subjects, however, should be handled tenderly.

A tree is hardly killed by cutting off the top-most boughs. Simple bathing is hardly a remedy for deep-seated ills demanding more general means of correction. We have not told all we have even thought upon the subject of the skin. We would like to say more, but we have a vision of Mr. Freas' waste basket.—*Germania Telegraph*.

Diphtheria.

Diphtheria was an almost unknown disease 20 years ago. To-day it has nearly assumed the proportion of an epidemic in many localities. It attacks adults as well as children, but its ravages are chiefly among the young and feeble. The dread which parents formerly felt of scarlet fever has given place to the dread of diphtheria, and the rapid and fatal character of the disease makes it more formidable than any other of the diseases to which children are peculiarly liable.

It is sufficiently well established that diphtheria originates, at least in very many instances, from defective drainage and sewer gas. The poisoned air and polluted water which are the conceded causes of typhoid fever are equally fatal in developing diphtheria.

Diphtheria is not a difficult disease to combat when it is treated in time. The distinctive feature of it is the formation of a false membrane in the throat. This marks its appearance in nearly all cases in the shape of grayish brown patches; and hence it is of the utmost importance to watch closely the throats of children who are apparently ill with cold and sore throat. In most cases there is fever and prostration in the early stages of the disease; though in rare instances the false membrane is formed suddenly and almost without warning. If the throats of ailing children are frequently examined, there will be little danger that parents will mistake incipient diphtheria for an ordinary cold. Scores of children have died of diphtheria who would undoubtedly be now alive had the grayish brown patches in the throat been discovered at their first appearance, and a competent physician been promptly summoned.

THE PULSE.—Every person should know how to ascertain the state of the pulse in health; then by comparing it with what it is when ailing, he may have some idea of the urgency of his case. Parents should know the healthy pulse of each child, as now and then a person is born with a peculiarly slow or fast pulse, and the very case in hand may be of that peculiarity. An infant's pulse is 140; a child of seven about 80, and from 20 to 60 years it is 70 beats a minute, declining to 60 at fourscore. A healthy grown person beats 70 times in a minute; there may be good health at 60, but if the pulse always exceeds 70 there is a disease; the machine is working itself out; there is a fever or inflammation somewhere, and the body is feeding on itself, as in consumption, when the pulse is quick, that is over 70, gradually increasing with decreased chances of cure until it reaches 110 or 120, when death comes before many days. When the pulse is over 70 for months, and there is a slight cough, the lungs are affected. The pulse decreases, when a recumbent position is assumed for any length of time, and is increased by exercise stimulants and the presence of food in the stomach.

ONESITY.—The best remedy is to eat moderately of sugar, starch, and butter, and make the diet largely of fruit and grains. It is a very simple matter, and requires no long labored article. Daily vigorous exercise should be taken, and in the morning a cold bath.

DOMESTIC ECONOMY.

Household Hints.

A lady in McGregor, Iowa, sends these: A strengthening liniment, good for lameness, weakness; also for bathing the stomach in cases of dyspepsia—take one beef's gall, two ounces of origanum oil, one pint alcohol; mix thoroughly; keep tightly corked; shake well before using.

One of the best cements for crockery is to mix lime with the white of an egg. To use it take a sufficient quantity of the egg to mend one article at a time. Shave off a quantity of time and mix thoroughly. Apply quickly to the edges and place firmly together, when it soon sets and becomes strong. Calcined plaster of paris will answer in place of the lime.

If brooms are wet in boiling suds ones a week they will become very tough, will not out a carpet, but last much longer, and always sweep like a new broom. A handful or so of salt sprinkled on the carpet will carry the dust along with it and make the carpet look bright and clean. A very dusty carpet may be cleaned by setting a pail of cold water out by the door, wet the broom in it, knock it to get off all the drops, sweep a yard or so, then wash the broom as before and sweep again, being careful to shake all the drops off the broom, and not sweep far at a time. If done with care it will clean a carpet very nicely, and you will be surprised at the quantity of dirt in the water. The water may need changing ones or twice if the carpet is very dirty. Snow sprinkled over a carpet and swept off before it has time to melt and dissolve, is also nice for renovating a soiled carpet. Moistened Indian meal is used with good effect by some housekeepers. The broom wears out carpets as much as feet do.

Cooking by Cold.

It is a curious fact, not generally known, that the action of intense cold on organic substances is similar to that of a high degree of heat, and that, when subjected to a very low temperature of heat, meat can be brought to a condition similar to its state when cooked by actual warmth. Quite recently a Hungarian chemist, Dr. von Sawiczawsky, who, it appears, has investigated all the various ways suggested for preserving meat (by chemicals, cooking by heat and hermetically sealing, etc.), and has found points of objection to all, has attempted the preparation of the material by subjecting it in a perfectly fresh state to a temperature of 33° below zero, Fahr., and sealing it afterwards in tins. The results obtained have been highly satisfactory; the meat on being removed from the cans appears, in point of smell and color, as fresh as if just taken from the butcher's stall. Although partially cooked, and thus requiring less fuel to complete its preparation for the table, it is entirely without the taste of meat which has been partially subjected to any heating process, and may be roasted, broiled, or otherwise treated, the same as if it were fresh. A commission appointed by the German government has lately conducted a series of careful and successful experiments upon the process; and as a final test two cassettes of the German navy, being about to circumnavigate the globe, have been supplied with a large stock. An extensive factory is being erected in Hungary for its manufacture.—*Sci Am*.

DISH WASHING.—Mrs. S. B. Sawyer, in the *Country Gentleman*, very pleasantly instructs how to wash dishes so as to make it "fun." Let me describe, by way of contrast, another method, which is anything but fun, to the intelligent looker-on at least. Wash the dishes indiscriminately, without regard to their different condition, and without scraping; put them dripping from the greasy suds into another pan, bottom up. When the pan is full, pour over them a dipper of hot water, and thus "make clean the outside of the cup and the platter, but within"—etc. Then take them directly from the water to towel, which is thus made soaking wet in a few minutes.

Dishes should always be drained a few seconds after rinsing, as it saves half the labor of wiping, and keeps the towel in better condition. Your correspondent refers to a draining rack, which is no doubt useful; but the plan practiced and taught by an excellent housekeeper of my acquaintance, was to drain the dishes on a cloth laid in the bottom of the sink. This keeps them from slipping and thus getting cracked, and also absorbs the water; and an extra dishcloth of good size, kept at hand for the purpose, will be found convenient. These homely tasks are honorable because necessary, and it is beneath the dignity of no lady to learn the best methods of performing them.

WASHING FLANNELS AND LINENS.—To whiten flannel, made yellow by age, dissolve one and a half pounds of white soap in 50 pounds soft water, and also two-thirds of an ounce spirits of ammonia. Immerse the flannel, stir well around for a short time, and wash in pure water. When black or navy blue linens are washed, soap should not be used. Take instead two potatoes grated into tepid soft water (after having them washed and peeled), into which a teaspoonful of ammonia has been put. Wash the linens with this, and rinse them in cold blue water. They will need no starch, and should be dried and ironed on the wrong side. An infusion of bay will keep the natural color in buff linens, and an infusion of bran will do the same for brown linens and prints.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance.—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, March 18, 1876

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Foot Lath; The State Geological Survey; Mining Engineers at the Centennial, 177. The Press at the Chile Exposition; The Mining Debris Question; Reversible Water Power Hoisting Machinery, 184. The Mining Committee's Report on the Debris Question; The Oppenheim Single and Double Buggy, 185. Patents and Inventions; Notices of Recent Patents; Gems and Precious Stones, 188.

ILLUSTRATIONS.—The Foot Lath, 177. The Oppenheim Single and Double Buggy, 185.

CORRESPONDENCE.—West Mountain Mining District, 178.

SCIENTIFIC PROGRESS.—The Practical Uses of Light; The Absorption of Hydrogen; Scientific Ballooning; An Ice Rink at All Seasons; Occulted Hydrogen in Explosive Antimony; Annual Variations of Temperature; Sunlight on Floral Development; Electricity and Light, 179.

MECHANICAL PROGRESS.—Sixty Foot Rails; Iron Vessels; Electric Light for Locomotives; Propeller Scows in Casings; A Domestic Steam Engine; Narrow Gauge Railroads; A New Mode of Gas Manufacture; A New Locomotive, 179.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 180.

MINING SUMMARY from various counties in California, Nevada, Oregon and Utah, 181-88.

THE ENGINEER.—Modern Engineering; Light-house Building Under Difficulties; Street Railroad Locomotion; Engineering Dreams being Realized, 182.

USEFUL INFORMATION.—How to Get Rid of Household Pests; A Hint to Young Mechanics; Origin of Railroad Gases—Different Versions; Spoken Languages; Things to be Remembered; A Triple Railway; Blast Furnaces in Great Britain, 183.

GOOD HEALTH.—The Skin: Diphtheria; The Pulse; Obesity, 183.

DOMESTIC ECONOMY.—Household Hints; Cooking by Gold; Dish Washing; Washing Flannels and Linens, 183.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 188 and other pages.

MISCELLANEOUS ARTICLES.—The Black Hills; Mining Affairs in Idaho; A Rich Stock Board; A New District—Aurora; Copper in the Foothills, 178. Silver Lead Ores, 182-88. Quartz Mining in Montana, 188. Tuscarora District, 190.

NEW ADVERTISEMENTS.

Iron Pipe, Dunham, Carrigan & Co., S. F., California Acclimatizing Society—Salt, Real Estate, Mines and Mineral Lands, Townsend, Wyman & Co., Philadelphia.

The "Press" at the Chile Exposition.

A prophet is not without honor, etc. We have a communication from Wm. C. Quincy, Santiago, Chile, as follows: "I have the pleasure to inform you that your publications have been awarded the Grand Bronze Medal of the Chilean Exposition, the highest award granted your class of publications." We modestly deck our cap with this new feather.

NEVER before in the history of Virginia City have the slopes of Mount Davidson been so completely covered and so great a depth with snow. Upon the north and northeast slopes of Mount Davidson the snow has fallen and drifted to a depth of from eight to 40 feet in the canon on the north side of the mountain. A day or two of warm weather would render the danger of an avalanche imminent.

THE fire at the Belcher mine on Saturday was confined to the rope house. The Belcher fire brigade, aided by the Liberty and Yellow Jacket hose companies, of Gold Hill, soon deluged the burning building with six streams of water, thus preventing the spread of the fire to the works.

THE Idaho papers state that many lies have recently been filed on mines in that Territory for work done on them.

The Mining Debris Question.

The mining debris question has received the consideration of two of the Assembly committees and two reports have been made. The Committee on Agriculture sets forth anew the farmers' grievance. It recounts the loss by covering fertile fields with the thick deposit from hydraulic washings; the danger of a thousand times greater damage which must result from the improved systems of hydraulic mining if no remedy is devised to counteract its effects. In the main the report of the Committee on Agriculture recites the same facts which we have laid before our readers in reports of farmers' meetings in the threatened districts and in the bill which was presented in the Assembly asking for a commission to examine the evil and report a way of obviating it. The report of the committee recommends the establishment of such a commission "to investigate and report upon the feasibility of utilizing the debris," and to co-operate with the engineers whom the United States Government is asked to appoint to examine the threatened danger to navigable streams from the same cause which lays waste the farmers' fields.

The report from the Committee on Mining acknowledges that damage has been done in some cases, but claims that the service of the mining population in affording a market for the agricultural productions of the foothill counties and the effect of mining enterprises in storing up water in winter to feed the streams in summer, are matters for the public good. It alludes to the fertilizing quality of the detritus and instances the effect produced by the earthy matters which have been deposited by the Nile. The report of the Mining Committee is perhaps as good a showing as could be made in the interest of the miners, and we publish it in full in another column of this issue of the Press. The miners agree with the agriculturists that the whole matter should receive a strict and complete investigation by scientific engineers, and petition the United States Government for a commission to execute this work. Thus the matter ends, and thus probably it will remain, a contested matter among rival interests, until some thorough searching shall discover the true adjustment of the difficulty.

This substitute for Assembly concurrent resolution No. 17, offered by the Committee on Mines and Mining, is addressed to Congress, and sets out the allegations of its agriculturists relative to hydraulic mining and its damage to agriculture, to rivers, harbors, cities and towns. That these allegations involve interests of vast magnitude, and engineering theories and practice of such intricacy, that the Government should appoint a board of engineers to examine and report upon the problems and all facts connected with hydraulic mining, and the disposal of the tailings in such a manner that no damage may be caused thereby. Upon the receipt of such a report the State and General Government can act intelligently and wisely upon the whole matter, without crippling the mining interest, or permitting the agricultural interests to suffer.

The Government should institute inquiry into the subject, because it has sold its gravel mine for the express purpose of their being washed out, just as it has sold land to the agriculturists for the express purpose of being tilled. Both classes are entitled to Governmental consideration and exemption on this subject, that means may be devised to remedy or alleviate the damages alleged.

That the navigable streams of the State are under the care of the Government, as also are the navigable bays.

That now when specie resumption is engaging the attention of the country, any steps to effect the production of gold mines become of national consequence.

The Government has in its pay competent engineers, unbiassed, and having no interests involved. If the State conducts the examination, it is feared those in one or the other interest will have a controlling influence in the Board, and thus give it a partisan character. The cost of such a commission to the Federal Government would be inconsiderable, while one by the State would be large, and the result not so satisfactory.

Therefore Congress is asked to take such action as may be necessary, and to detail competent engineers to a commission to investigate the subject.

MINT APPROPRIATIONS.—The amounts recommended by the House Appropriation Committee for the salaries of officers and clerks of the San Francisco mint and Treasurer's office, are fixed in accordance with the committee's general policy of cutting down pay 10 per cent. and the force 20 per cent. throughout all the departments. The item for wages of workmen and adjusters is \$225,000. The total appropriations of every description for the Carson mint are \$48,350, against about \$210,000 last year. No appropriations are cautioned for either superintendent or collector, and the item for wages is reduced to \$10,000. In short, the committee proposes to make the institution merely an assay office.

THE amount of bullion taken out and shipped from that portion of Nevada county known as the Ridge, for the year 1875 is \$1,154,817. The Transcript believes that with the proper facilities and a sufficient supply of water this amount can be doubled yearly for the next 25 years.

Reversible Water Power Hoisting Machinery.

There is no limit to the discoveries of science, and no difficulty of a mechanical nature which the man possessed of a true inventive spirit is willing to admit as unmountable. While the inventor must have considerable originality in the complexion of his mind, yet this characteristic alone is not sufficient to invest a man with the honored name of inventor. He must not only have the genius to conceive of new combinations of the mechanical laws, but also the strength of will and moral courage to give practical value to the creations of his brain. When an individual forsakes the beaten track of experience, and endeavors to give a tangible form to the devices which have been conjured up by his fertile imagination, the sneers and derision heaped upon him by lesser men than himself are often a greater strain upon his moral nature than the original ideas which are struggling into mechanical shape are upon his intellectual forces.

A Difficult Problem.

The construction of a reversible water power to supersede the reversible steam engine used for hoisting purposes in our mines has been regarded as an impossible task by some of the ablest mechanics of the day. All of them readily concede the immense importance to mining industry of an invention of this kind, but the many obstacles in the way of its attainment led them to place it beyond the range of possibility. There were two principal reasons assigned why water power could never be utilized for hoisting. 1st. That water could not be brought under such perfect control as would enable the engineer to regulate the speed of hoisting or lowering to suit the miners in the shaft. Human life is involved in the matter of hoisting, and it is therefore necessary that the bucket, ascending or descending, should be made to answer readily the wishes of the miners, as is now done by steam. It has long been ascertained that the mere hoisting and lowering could be accomplished with water as the motive power, but the real difficulty was to instantly increase or lessen the speed so as to guard against accidents. The second difficulty was this, if the water gate was so arranged as to shut off the water instantly in the pipe, the concussion of the water would be very apt to burst the pipe. So that while it was requisite to shut off the water suddenly at times to gauge the speed of the bucket, or bring it to a standstill, this pent-up water would become a source of peril from the violence of its reaction.

The Problem Solved.

It was reserved for the genius of a mechanic of Amador county to master this problem, and thereby impart a new impetus to the mining interests of the State. S. N. Knight, of the firm of Knight & Co., mechanists and foundrymen of Sutter Creek, has been quietly experimenting for the last three years with the view to remove the difficulties surrounding this subject, and now has the satisfaction of seeing his labors crowned with success and his most sanguine expectations realized. Mr. Knight is deserving to be classed as one of the best mechanists in the State. In addition to a thorough knowledge of machinery and the laws of mechanics, he possesses to an eminent degree the faculty of combination and an undaunted perseverance that mark all noted inventors. He has already made several important contributions to the list of patented inventions. His improved water wheel was patented over a year ago by Messrs. Dewey & Co., of San Francisco, and is rapidly asserting its superiority over all others in use. Seventeen of these wheels are now running in Amador and adjoining counties. Among the mills run by Knight's wheel, we may mention the following: The Oneida, 60 stamps; the Consolidated Amador, 40 stamps; the Lincoln gold mining company, 40 stamps; the Keystone Consolidated, 40 stamps; and the Original Amador, 40 stamps. It is, however, in the adaptation of water power for hoisting works that Knight's reputation as an inventor will henceforth be known.

The Keystone Hoisting Works.

Some months ago the Keystone mining company determined to sink a new shaft to facilitate the working of their mine. The enterprising superintendent, O. C. Hewitt, whose readiness in adopting the latest improvements has made the Keystone the best equipped mine in the county, if not in the State, instructed Mr. Knight to construct first-class hoisting machinery over the new shaft, leaving him to determine as to the character of the works. Here was an opportunity to test his long-cherished theory of hoisting by water power, which in his own mind had already passed the theoretical stage and become an accomplished fact. He immediately set about the work without revealing the nature of his designs. It soon became noised abroad that he was trying to put up hoisting works to run by water, and the enterprise became the butt for the ridicule of every ordinary mechanic in the county. The idea was laughed at as absurd, and a complete failure was predicted. The engine and boiler makers were particularly incensed at the undertaking, which, if successful, threatened to curtail their business to an alarming extent. To

the credit of the superintendent of the mine be it said, that he remained undisturbed by these would-be prophets. He had faith in the ability of Knight to fulfill his engagement, and wisely refused to interfere in any way with his plans. About three weeks back the works were brought to completion, and everything worked to a charm. The whole machinery is as easily manageable as the steam engine. Every desirable point in the engine is retained by this novel water power. The hoisting and lowering is conducted with the same precision, and the speed regulated as readily as by the old method. The voice of opposition is silenced, and the laugh turned in favor of the inventor.

The Invention Explained.

During the week we have taken the trouble to visit the Keystone mine for the purpose of inspecting the contrivance, and will now proceed to explain its essential details as far as our limited acquaintance with the technical terms will allow. There are two water wheels, each four and one-half feet in diameter, both of Knight's improved pattern. One of these wheels is for hoisting and the other for lowering. The water is conducted through a 15-inch pipe, with a fall of 150 feet. Within a few feet of the wheels the pipe branches into two distinct forks, each wheel being provided with its own nozzle. To change the water rapidly from one wheel to the other without endangering the pipe is the point wherein the merit of the invention lies. To accomplish this, a simple but efficient device is brought into use for working the gates of the two wheels, to which gates the name of "power gates" has been given. Each gate is furnished with two cylinders, cast in one piece, and the small cylinder has two pistons acting as a balance valve. When moved by the engineer, a port hole is opened, which admits the water into the large cylinder, the water forcing back the piston and rod that pass through the cylinder end connect with the slide valve of the water gates. By this means the gates are moved almost instantly, and the flow of water can be graduated to insure the desired speed of the ascending or retreating bucket. The steam engine, used for hoisting before the water power was constructed, is still retained, so that hoisting may be carried on in the event of a temporary suspension of the water supply. It needs no change of position in the reverse lever to operate either by steam or water. The water wheel power is connected with the engine shaft by a large pulley and belt, and in running by water the connecting rod is simply disconnected from the engine.

The Importance of the Invention.

It is scarcely possible to over-estimate the importance of this invention to the mining interests of the foothills. One of the principal items of cost in mining is the expense of fuel for the generation of steam. The substitution of water for steam in running mill machinery, has already materially reduced the cost of mining. By this adaptation of water power for hoisting, steam can be entirely dispensed with. In the case of the Keystone, as soon as the new shaft is completed, all the hoisting will be done by this water power and steam will not figure in the operations at all. The water, after running the hoisting works, is again utilized in feeding the stamps. So that by and by the entire expense of hoisting by steam will be saved. Some idea can be formed of this saving, when it is said that about fifteen cords of wood are now consumed every day in running the engines of the Keystone, and that the cost of this fuel is equal to at least \$1 for every ton of ore taken from the mine. It will thus be seen that this reversible water power is destined to mark the dawn of a new era in the history of mining enterprise in California.—Amador Ledger.

THE BONANZA CONTRACT.—A contemporary announces the subjoined as the contract between the Government and Flood & O'Brien: The Consolidated Virginie and California mining companies propose to sell \$20,000,000 of Dore bars, to be supplied at the Carson Mint, and to take in payment the amount of gold contained therein, and five or four and a half per cent. bonde at market rates. The price of silver is to be governed by the London rate, less transportation from New York, plus the premium on exchange; deliveries to be commenced immediately, and to be completed by the Fourth of July.

THE Associated Country Press of the Pacific coast met on Monday at the Occidental hotel. This association represents 30 of our rural papers, and one of its main objects is to do away with "patent outsiders," and to obtain in their place the full benefit of all city advertising now sent to them in this wholesale fashion. The next day (Tuesday) Mr. Glancy, of Auburn, was chosen as their agent in this city, the appointment being left to the Directors. The association adjourned sine die.

RICH gold discoveries are reported from St. George, Utah, assays from the surface dust going as high as \$1,000 and \$1,500 to the ton. Brigham Young is on his way from Salt Lake to inspect the new fields, and if they are found to be of value, will call down a force of his adherents to keep out Gentile miners and prospectors.

THE present season has been very disastrous to the Southern Pacific railroad company, costing them over \$100,000 for repairs, principally owing to the shifting by the heavy rains of the sandy soil upon which the track is laid.

Snow is two feet deep on Mount Diablo.

The Mining Committee's Report on the Debris Question.

The report of the Committee on Mines and Mining opens with the statement that mining and agriculture are the chief industries of the State, and between them there is a condition of mutual dependency. Agriculture was called into existence in California by the necessities of the mining population, and now the larger part of farming produce is consumed at home, and of these consumers is the mining population, constituting one-fifth of the entire population.

History shows that a country which for years largely exports its cereals, impoverishes itself. Wheat is the only practical export for the farmer, and hence wheat chiefly is sown; but if one staple only is planted for many years, the result will be disastrous to farming interests. To foster mining, and increase the number of home consumers and establish a home market, encourages varied agriculture and enables rotation of crops to preserve the fertility of the soil. So, any act crippling mining, will, almost in the same measure, bring disaster to the farmer.

Gold Production.

The gold production of California from 1849 to December, 1875, is estimated at \$1,146,000,000, of which probably \$900,000,000 came from the ancient gravel deposits of the State, directly or indirectly. From 1849 to 1859 these fields were washed by placer mining. The great fertile plains of the Sacramento and San Joaquin were created by the soil and gravel washed by the slow processes of time from the mountains, while the gold was left in the streams for the pioneer miners. These placers being exhausted, in imitation of nature, the miner began with the hydraulic process, which has grown to be the most important mining interest in the State, and is now bringing renewed wealth and prosperity to many of our once famous mountain counties. About \$130,000,000 has been expended to date in canals, reservoirs, etc., for working gravel channels. The yield in 1875 from these mines, despite an unfavorable season, amounted to about \$12,000,000, and will increase in the next five years to \$20,000,000 per annum. Many large hydraulic enterprises are on the eve of becoming productive, and hence the foregoing estimate is just. This great yield represents an enriching capital of fully \$200,000,000, and will support 120,000 souls and indirectly assist the farmer, manufacturer and commercial dealer.

Water Held in Reservoirs.

The miners have large numbers of reservoirs, which are filled with water during the winter floods, to be exhausted in summer and autumn. Many large reservoirs are now being constructed and will help decrease the flow of water in the rivers in winter, and in aiding in a supply for navigation in the summer. The united storage capacity of these reservoirs will, within two years, amount to an increased stream during the dry season of fully 70,000 miners' inches, being a flow of 1,800 cubic feet of water per second. If this was used for irrigation it would bring into cultivation 350,000 acres of foothill lands. Should mining cease and the value of the mines be extinguished, the mining counties would be destroyed and all the taxable property in the state would be seriously diminished, and the tax rate thus raised to the whole people.

The Damage Done.

The debris has done much damage to farming lands in the Yuba and Bear river valleys, and incidentally to lands on the Feather and American rivers, and has filled up the bed of the Feather river, somewhat effecting its navigation.

Whether the Sacramento river has been injured is doubtful, and engineering only can develop the real facts in that case. The flood of 1861-2 caused the first considerable amount of damage, and since has been increasing until now 30,000 acres, perhaps, of arable land have been covered with detritus from the mines. The damage is judged to be not over \$3,000,000, estimating the land at the high price of \$70 per acre, and allowing a liberal sum for damage to Marysville. As the beds of the Yuba and Bear rivers increase in width, their future vertical increase in the height will be diminished, though the mining debris may be greatly increased.

The mountain canons receive the tailings first, and the amount carried down in solution becomes less and less, until at Sacramento, by experiments made by Dr. Logan, the proportion by weight of earthy matter is to the water as one is to 1,000. This would make by bulk about one to 200, and is less than is carried by many of the world's great rivers. Most of the sediment carried by the Sacramento and San Joaquin rivers is finally deposited on the mud flats of the Lower Sacramento and in Suisun and San Pablo bays. Its entire amount, excepting Dr. Logan's experiment as correct, would be represented by an annual deposit of one square mile filled eleven feet in depth.

Debris Useful for Fertilizing.

The Nile brings down in its waters about twice as much earthy matter, and by a judicious system of irrigation is nearly all deposited upon the fields of Egypt. This has resulted in increasing the vertical height of the fields of Heliopolis, near Cairo, about 60 feet, and to the fertilizing properties of this deposit is due the continued fertility of the Egyptian soil, which produces now as abundantly as it did in the days of Jacob.

Irrigating With Surcharged Water.

The experience of many mountain farmers

who have used for irrigation water charged with mining sediment, has fully demonstrated its fertilizing properties, and private corporations in Butte, Yuba and El Dorado now propose to irrigate mountain slopes with it to fertilize the soil, and are acquiring lands for that purpose. If the coarser tailings are confined to the mountain lands, and the finer tailings deposited on the low lands of the Sacramento, they would be raised, fertilized and protected from overflow. The erosion by running water of the western slope of the Sierra has already filled these low lands to their present elevation, and this proposed measure is simply an imitation

Commission of Engineers to investigate the whole subject. The committee therefore recommends a substitute for Assembly concurrent resolution No 17. The report is signed by Representatives Birney, Blue, Briceland, Dunlap, Crutcher, Griswold and Koutz.

The Oppenheim Single and Double Buggy.

The Oppenheim buggy, which we illustrate on this page, is a California invention just patented, and a very ingenious one at that. Its peculiarity consists in the arrangement of the

FIG. 1. OPPENHEIM BUGGY, ARRANGED FOR ONE SEAT.

of nature, except that it is proposed to do in a few years what nature would require centuries to accomplish by natural causes. All successful protecting levees on tule lands have been built of mining-washed earth.

What Can be Done—Suggestions.

The committee think some plan can be de-

seats, by which it can be instantly changed from a single seated buggy, as shown in Fig. 1, to a two seated rockaway, as shown in Fig. 3. The ingenious mechanism by which this change is accomplished is exceedingly simple in detail and adds no material weight to the vehicle.

FIG. 2. DETAILS OF CONSTRUCTION OF OPPENHEIM BUGGY.

vised by engineering talent to prevent the damage complained of in a great measure, and so as to use the debris to the building up and reclaiming of now unproductive territory. The State and Federal Government should take action, says the committee, for the relief of those

There are, moreover, no unsightly bars or rods to support the movable seats, but everything is covered in, so that the general arrangement is neat, as such things should be. This is a great improvement over the so-called "jump seat" buggies, which have heretofore had such

FIG. 3. OPPENHEIM DOUBLE BUGGY AS A ROCKAWAY.

already damaged and now being damaged by mining tailing deposits upon their farms.

The committee further considers the vast importance of the subject, its relation to the prosperity of the country and its financial condition, and concludes by advising that Congress be memorialized for the appointment of a

a reputation for comfort and beauty.

The Single Buggy.

When arranged with but one seat, the vehicle is of no greater dimensions than an ordinary buggy, viz: 20 inches from dashboard to seat, 14 inches across the seat, 14 inches to rear end, making it four feet long in all, with no bars or

props sticking out behind. It then has the appearance shown in Fig. 1. In this form it is adapted to all the usual services required of an ordinary single seated buggy, but possessing the additional advantage of a capacity of enlargement at a moment's notice, in case more than two persons are to ride.

Operation in Making the Change.

To double the seats, the hind seat, B, (Fig. 2,) is lifted by the handle, h, from the front seat, C, into which it fits snugly (in the case of the single seated buggy), and pulled back as far as the stop joint, f, of the regulating bar, c, will permit. It then assumes the position shown in Fig. 2. Then the whole body is pushed forward by the lower handle, l, the body sliding on the bars, d, d, which pass through the rings, e, e, which are fastened on the supporting frame, g. By this means the front seat and dash are advanced 10 inches, while the hind seat, B, drops on to and is supported by the side panel, A. The buggy is then

A Two Seated Rockaway.

As shown in Fig. 3. The rockaway has all the proportions of a vehicle built expressly for two seats. The body is apparently lengthened 15 inches, by throwing the hind seat entirely behind the sill, where it is held firmly in position by the steel bars, a, a, as well as by the bars c, c, which latter also regulate the action when opening or folding the seats, and prevent the body from sliding backward or forward when in position. The length of the body is now as follows: from dashboard to front seat, 20 inches; front seat, 14 inches; space between the seats, 14 inches; width of hind seat, 15 inches; total, 63 inches. Both seats retain their full width, an important point, as the steel bars, a, a, drop into the grooves b, b, when the seats are folded. There is ample room for the knees and feet between the seats, and above all, it is as easy to get in and out of the behind as in front, a facility which no vehicle of this kind has offered until now.

Although this device may seem complicated from the description, at first glance, it is by no means so, being so simple in construction as not to be liable to get out of order, and if it should, any carriage maker or even blacksmith could repair it. By the slide motion of the body the weight of the seats is equalized, and either spring is relieved of too great a pressure, as would be the case if the seat merely dropped back without the body sliding on the frame. When arranged as a single buggy the seat comes back in its proper place, and when double the front seat is forward, so as to equalize the weight on the springs. The top is so adjusted as to be used as a single buggy top or extension top at pleasure, or the buggy can be built with the so-called stationary top. Livery stable keepers will easily see the advantages of a vehicle of this sort, as will those who do not desire to keep two buggies, but sometimes need a single, sometimes a double buggy. The Oppenheim buggy as made at present weighs about 400 pounds, without the top, and the price does not much exceed that of an ordinary single seated vehicle. Those desiring further particulars can apply to the agent, E. Steele, 13 Merchants' Exchange, in this city, or M. T. Holmes, the manufacturer, on Sutter street, near Stockton.

Bonanza Mines.

It will be remembered that about a year ago the proposition of cutting up the stock of the Consolidated Virginia mine was discussed, and there was a strong power in favor of taking that course, but finally the consideration of the question was postponed. It has now come up again and is definitely decided on. The increase of stock will be five of the new shares for one of the old. The capital will then be \$54,000,000, and the dividends per share will be paid in proportion. If anybody wants to buy any bonanza he will have a better chance now than when a single share was worth \$490.

Hale & Norcross is to be divided up seven for one, which will bring another low priced stock. The Consolidated Virginia is yielding at the rate of \$100,000 per day. The Mexican has developed not only a fine prospect of rich ore at the south end, but also struck good milling ore in the bottom of the winze, on the north line, 50 feet before reaching the 1465-foot level, which looks as if a rich and continuous body of ore the full length of the mine was going to be found. The Sierra Nevada has just opened a station and commenced the development of the ledge at the 1500 foot level, a point on the ledge that must be looked to with deep interest for some time to come.

MINING DITCHES.—Hilburn's bill, introduced in the Senate, provides that all water companies organized for the purpose of furnishing water for mining purposes must supply without distinction or discrimination all persons operating mining claims along the line of or adjacent to the ditch, flume, pipe or aqueduct through which water is supplied to customers to the extent of their capacity to so furnish the same, and at their regular schedule of rates. Any company refusing to supply a proportionate quantity of water to any person entitled thereto shall, upon tender of payment therefor, be liable to such person in damages to treble the amount of the sum so tendered.

MINING ENGINEER.—Attention is called to a new advertisement of a mining and civil engineer of over 20 years' experience in the United States, who has recently taken up his residence with his family on this coast.

(Continued from Page 182.)

this work, it may be stated by way of preface that the ores here occur mostly in large and regular fissures, the latter running along the steep mountain side generally parallel with each other and not far apart. Under this arrangement it becomes possible to cut off at great depth a considerable number of these lodes by means of a comparatively short tunnel run at right angles with their course. Availing themselves of these conditions, the above company, who are large owners in the principal series of lodes here, determined to commence an adit of this kind, the veins to be intersected by it consisting of the Buena Vista, lying further up the mountain, followed by the Union, San Felipe, Omega, Santa Maria, Jefferson, Cainan, Guadalupe, Guaymas, First and Second lead mines, San Benito, Alpha and Ignacio. These are all broad, well-defined, fertile ore channels, easily traced in a linear direction for a long distance, each of them having a number of different company claims located upon them. The Potosi own portions of nearly all the more valuable of these lodes, besides having interests in mines situated elsewhere in the district. These lodes occupy a belt less than 3,000 feet in width extending north and south along the face of the mountain, here so steep that the tunnel will be 2,140 feet below the surface when it reaches the Buena Vista lode, and 300 when it reaches the Ignacio, the first lode cut, unless a blind one should be sooner encountered, the entire tier of veins being intersected at an average depth of about 860 feet. This tunnel was commenced several months since, and has now reached a length of over 500 feet, the work of excavation having thus far been performed by hand. To facilitate its progress, a machine drill of the Burleigh patent has been purchased at a cost of \$15,000, and will soon be in operation, through the aid of which it is expected the tunnel will be completed in a year from the time the machine is started. This adit is 8 feet high and 10 feet wide, and will cost about \$100,000.

Advantages of the Tunnel.

In few localities would a work of this kind secure greater benefits to both the proprietors and the adjacent mine owners than here. Many of the lodes in this belt have now been worked by means of shafts to depths varying from 500 to 700 feet, as far down as operations can be prosecuted without costly hoisting works. The slope of the mountain above the mouth of the tunnel is steep, rendering it difficult to get the ores down if brought to the surface through shafts, whereas the ground below is so flat that they could be easily removed. By drifting in on the tunnel, the companies owning on this belt would be able to attack the veins down where the richer ores are supposed to exist, the deposits here having been found to improve downward in a remarkable manner. By working through this adit all the cost of drainage and of hoisting their ores, and afterward bringing them down on the surface, would be avoided, not to mention other material gains effected. The proprietors of this tunnel will in fact be able to largely control this belt of mines. All blind lodes cut they will take as a matter of course, and of these a good many will most likely be encountered. Several have already been met with, two of them carrying ore of astonishing richness. No competing tunnel can be run, for the reason that this company have secured the only eligible site here. All claim owners interested have concluded to get along with their present shafts and inclines until the big tunnel is completed, and then work through it, paying a moderate royalty for the privilege. A considerable body of water was recently struck in this tunnel, and as this has heretofore been a scarce article in Cerro Gordo, selling at high rates, this abundant flow must yield the company a handsome revenue, the probability being that the supply will increase as the tunnel is advanced.

The Character of Ores, Cost of Freight, etc.

The ores in this district consist of carbonate, sulphureta, and the chlorides of silver, with large quantities of argentiferous galena. Both the milling and smelting ores are extremely tractable. The former carry from \$150 to \$500 per ton of silver and \$90 of lead, the lead more than covering the cost of milling, smelting, and transporting to market. The geological formation here is composed mainly of alternating bands of slate and limestone, being favorable alike to permanence and wealth. The cost of freight bullion to San Francisco is now \$50 per ton—rates, as the railroad approaches, being steadily diminished. In the course of a year or two this district will probably be connected with tide-water by means of two railroads. For an enterprise combining so many of the elements for success and as well administered, a very prosperous future may reasonably be expected. The finances of this company are in a healthy state, and its business affairs in excellent hands. As a mining captain, John Simpson, having charge in the field, has no superior; while it may safely be said that what Jaa. A. Pritchard, President of the company, does not know about mines and mining matters has not yet been found out by any one else. With a tunnel designed to secure so soon the deep development, ventilation, and drainage of this important group of mines, and with railroad transportation to tide-water so close at hand, the prospects of Cerro Gordo and the mining districts adjacent are of an altogether encouraging kind.

Rich mines have been discovered in Big Horn and Owl Creek mountains, Wyoming.

Quartz Mining in Montana.

Every day brings reports from the quartz mining districts of improved prospects in the lodes, and indications of increased activity in this important branch of mining industry during the coming season. From Bannack, Trapper, Vipond and Butte we hear cheering news, and are assured that if but a tithe of the present expectations are realized, that there will be a large augmentation of the yield from our gold and silver mines, and that another year will see the demonstration of the fact that Montana possesses mineral-bearing lodes in no whit inferior to those of the chief hulkion producing States and Territories. Already the shipments from Phillipsburg are marvellous, compared with the former yield from the mines in that region, and in a short while their producing capacity will only be limited by the facilities for treating the ore as they are extracted from the mines. The failure of the past have brought experience—dearly bought, perhaps, in many instances—and this virtue, which is proverbially said to "make fools wise," combined with energetic effort, will place our quartz minea in their true light, and develop the hidden wealth in our mountains. Steady, persistent labor, aided by judiciously invested capital, are bringing to the light minea of wealth which would gladden the eyes of the most sanguine prospector, and we speak by the card when we say that the future of Montana, as a mineral-producing region, never appeared more bright than it does to-day. With the almost daily discovery of mines, and their successful working to encourage us, what may we not predict of the results of quartz mining in Montana in the near future?—*Montanian*.

STEEL SHOES AND DIES

FOR QUARTZ MILLS.

Made by our improved process. After many years of patient research and experiment we have succeeded in producing STEEL SHOES AND DIES for

Quartz Mills, which are unequalled for Strength, Durability and Economy.

Will wear three times longer than any iron Shoes.

BUILDERS AND CONTRACTORS

Of Quartz Mills, Pans, Separators, Concentrators, Jigs, Hydraulic Rock Breakers, Furnaces, Engines, Boilers and Shafting, and General Mining Machinery in all its details, and Furnishers of Mining Supplies. All orders promptly filled.

MOREY & SPERRY,

88 Liberty street, N. Y.

Examination solicited.

From year to year they have been improved under the personal supervision of Mr. Hoadley. The latest great improvement is the REGULATING CUT-OFF, with balanced valve, thus giving it all the economy and increased power of the most thorough-built Corliss Stationary Engine. By this addition, a 15-horse power Hoadley Portable can be run at over 40-horse power, if required. As a Threshing Engine, the Hoadley is the leading engine of the country. It has no equal. For prices, etc., send to

TREADWELL & CO., S. F.

Mining Superintendent.

E. B. Smith, for nearly twenty years engaged in the direction of mines and mining enterprises, can be engaged to take charge of any legitimate mining enterprise. Mr. Smith thoroughly understands the "Sonora" process of chlorination and lixiviation, being the originator of the same, and the erection of all machinery and furnaces for the treatment of rebellious ores. Office—439 Bush street, S. F.

(Continued from Page 181.)

progress, the water at the bottom no longer giving any trouble whatever.

ELY DISTRICT.

LOCAL MATTERS.—Pioche Record, Mar. 6: The amount of bullion shipped from Pioche during the month of February was \$180,980.98, a little less than for the month of January. This is accounted for by its being a short month. The Alps mill and mine continue to make good returns, having turned out \$13,000 in bullion this past week. The American Flag mine is running night and day with fair success. The repairs to the mill are almost completed and it is expected it will start up about the 6th of this month. The pump of the Raymond & Ely is still working successfully and running eight strokes per minute, keeping the water at a low stage. On Friday the pump was stopped for eight hours to enable them to put in a plunger. When the pump commenced work again there were 50 feet of water in the shaft, which will doubtless be reduced by this morning to three or four feet. Work in the mine is continued vigorously on the 8th, 9th, 10th and 11th levels. The Nevada Central railroad is conveying the usual amount of ore to the mills at Bullionville and the bullion yield shows improvement.

RAYMOND AND ELY.—Work is steadily proceeding with on the 8th, 9th, 10th and 11th levels of this mine, the 11th being pushed ahead rapidly. The amount of ore extracted comes up to the usual average, 75 tons. The various levels are looking well and show no decrease in the ore. The pump is giving satisfaction in every particular.

AURE MINE.—The production of bullion at this mill last week amounted to \$13,000. Ten stamps were run on ore from the Alps mine and for the last three or four days the other five stamps have been run on custom ore. The above returns show that good work is being done.

NEWARK MINE.—This mill during the past week has been busily engaged running on chlorides' ore from the Meadow Valley mine. Among the shippers are Ed. Boyle and Joe Kennedy.

TYBO DISTRICT.

THE TIMES.—Oor. Eureka Sentinel, Mar. 9: Our late heavy snows have rendered the burning and hauling of coal almost impossible, in consequence of which our furnace has closed down. About the 20th inst. the new 60-ton furnace will be completed, when the company contemplates starting it. It thinks that from that time on it will be able to procure sufficient coal to run at least one furnace all the time. Our little burg is considerably agitated at present on the subject of Chinese labor. Some of our heavy coal contractors are thinking of employing them. There are no doubt men who can be worked to a much greater profit than white men; but while it will enrich individuals, whether it will impoverish the mass of workmen is the question to be decided. It is rumored here that there is a society formed by the miners and coal-burners, comprising 75 members, to prevent the introduction of Chinamen as coal-burners. We do not entirely approve of them taking away the work of our countrymen, still the arbitrary measures which some propose taking to prevent it are to be severely denounced. It is adopting crime to prevent an evil. Our mines—the 2 G and Bunker Hill—are looking better than ever. Working them has only disclosed larger and richer bodies of ore, and enhanced their value. The hoisting works on the large shaft of the 2 G have been found to be too light and insufficient for the work, so the company will shortly place new and heavier machinery in their place.

Taz Gila mill, at Revella, has closed down, it is said, for lack of ore. But where nobody is admitted to a mine it is difficult to tell what they have in it. They have produced too much bullion already to stop entirely now.

Our latest news from Belmont represents that town to be in a fever of excitement over the wonderful strike in the South Barcelona mine, at Spanish Belt district. It is said that they have run into a body of \$600 ore in the tunnel, and that they are now into it 45 feet without any sign of a foot wall. We can deduct a good deal from this for exaggeration's sake, and still have a big thing. There is no doubt they have struck a bonanza.

Oregon.

VIRTE MINE.—Bedrock Democrat, March 1: On last Monday we, as well as a large number of our citizens, visited J. W. Virtue's bank to see and lift the bullion from the Virtue mine, and the result of 15 days' run of the Virtue mill from the rock that is now being taken from the mine. The bullion weighed 664 ounces and is worth \$12,616. The longer this mine is worked the better it proves itself to be. Superintendent Hyde understands his business thoroughly, and has brought the work to such a regular system and to such perfection that the same amount of work is done with one-third less labor than the same formerly required. The new working shaft has reached a depth of 175 feet, and is being pushed ahead as fast as possible; another contract will be let as soon as the present 100-foot contract is completed. The new shaft, if completed, will make the work will be very much facilitated, and larger bullion shipments will be the order of the day. Lumber is being landed now for a new shaft house, and new hoisting machinery will be put in position immediately. The machinery is all on the ground.

Utah.

STAR DISTRICT ITEMS.—Oor. Salt Lake Tribune, March 2: Since my last, the Big Bonanza in San Francisco district has changed hands. The lucky purchasers are Matt Cullen, Denney Ryan, Green Campbell and A. J. Ryan. The price paid, I am informed, is \$25,000. A small price for so nice a piece of property. There are also a number of other prospects in the district which are yielding ore, and looking finely. Among them is the Battler. A good body of ore has been struck, and the owners are happy. Mr. Schappell and Mr. Martin, of Beaver City, have lately purchased a claim known in this district as the Longevity. It is now being fed with miners, powder, drills and other useful articles. Pure ore is light and it looks well. They have also purchased a half interest in the Self Riser, and the way ore of a high grade is being raised, it is not misnamed. Many other prospects are being worked and look well. A smelter is to be erected near the Big Bonanza, in San Francisco district. This, with the smelter at Troy and Shantree, makes three. Lincoln district now severely feels the need of a railroad. The machinery for the big mine there has now been on the road for a long time, and work is at a standstill in consequence of it. The mines and prospects in and around here look so encouraging that the Black Hills fever has removed, but very few from our midst.

BRADSHAW DISTRICT.—situated about four miles south of Lincoln, is becoming one of the leading ore-producing districts of Beaver county, and its mines are being developed by their owners, and are proving to be of great value. The formation of this district consists of limestone, quartzite and granite, and the mines of the same show quantities of milling and smelting ores, the former character of ore predominating as far as developments have been made. The milling ore goes about \$300 a ton, and the gold, carrying but a small percentage of lead. The ore of the Cave mine, which is the oldest location in the district, and which has been developed to a considerable extent, shows in all its drifts, inclines and shafts, a large body of milling ore, carrying chlorides, some horn silver and gold.

SEVERAL ore mills in the vicinity of Gold Hill and Silver City have been compelled to suspend operations on account of scarcity of wood and the bad condition of the roads.

PATENTS & INVENTIONS.**A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.**

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington D.C., Mar. 14th, 1876.

FOR WEEK ENDING FEBRUARY 29TH, 1876.*

ELECTRO-MAGNETIC REGULATORS FOR STEAM ENGINES.—Stephen D. Field, S. F., Cal.

ELECTRICAL SWITCHES AND CUT OUTS.—Stephen D. Field, S. F., Cal.

SADDLE TREE (papier mache and cork dust).—Pemberton B. Horton, S. F., Cal.

WHEELS FOR VEHICLES.—Charles Lea, Florin, Cal.

ADJUSTABLE MOLD BOARD SCRAPER.—Frank O. Millikan, Santa Cruz, Cal.

VEHICLE SEATS.—Frederick Oppenheim, S. F., Cal.

CLOTHES LINE.—Lorenzo Sweet, S. F., Cal.

SHOES.—Hippolite Von Haverbeke, S. F., Cal.

QUARTZ MILLS.—Samuel H. Cowles, Sacramento, Cal.

ROTARY CULTIVATOR.—George E. Hopkins, W. T.

*The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

PROCESS FOR PRESERVING THE WOOD OF MANUFACTURED IMPLEMENTS.—Charles Lea, Florin, Sacramento county, Cal. This invention relates to an improved device for securing a permanent saturation of the wooden portions of tools, implements and machines with oils or other liquid preserving agents, so that the wood will be both preserved and prevented from shrinking and swelling. The invention is specially valuable for preserving the wood work of wagon and carriage wheels. The inventor makes a groove or channel in the face of the piece of wood, which extends its entire length, and this groove or channel is filled with oil or other liquid wood preserving agent. He then covers the groove by securing a metal plate over it to prevent the escape of the oil. In the construction of wagon and carriage wheels, in order to preserve the wooden felloe and prevent it from shrinking and swelling, the groove is made in the face of the felloe so as to extend entirely around the wheel. The tire is then shrunk on over the felloe so as to make a perfectly tight fit all around. A hole can then be drilled through the tire so as to communicate with the groove, through which it is filled with oil, after which the hole is stopped up with a plug. The hub is preserved by making a groove around each end underneath the bands, and filling them with oil. By boring a hole from the bottom of the groove on the felloe centrally through each spoke, the spokes can be supplied with preserving liquid.

IMPROVEMENT IN SHOES.—Hippolite Von Haverbeke, S. F. This is an improvement in the construction of gaiters and consists in the combination with such a shoe of an elastic piece, which is fitted across the instep. In this class of shoes it is almost always necessary to alter the buttons where the shoe crosses the instep, in order to fit them to different forms of feet, and even when fitted new shoes are apt to make the feet sore. In these improved shoes an elastic piece of webbing is fitted into the upper of the shoe, just at the point where the part which surrounds the ankle meets the upper of the shoe in front, and this web extends a short distance past from the lowest point of union of the two, so as to cover the overlapping lower ends of the part which covers the ankle. The buttons are set on above the webbing in the usual manner. By this construction the shoe is easily fitted to any foot, whether the instep is high or low, and will always be easy to wear. A considerable saving is effected in cutting the uppers by leaving off the points which would be necessary if the webbing were not used.

CLOTHES LINE ELEVATOR.—Lorenzo Sweet, S. F. The object of this invention is to provide a device for making a small space available for the purpose of drying clothes, and it consists in the employment of a series of transverse or other frames, suitably guided so that by means of pulleys and cords, and an operating windlass, the lines can be elevated successively as fast as filled, and to any desired height. By this device the inventor utilizes a very small space of yard room to dry all the clothes which may be necessary, and the operation will be very easy, as the upper line being stopped at a suitable

height above the ground can be filled with clothes, then elevated out of the way, at the same time bringing the second line or lines to the proper height, and thus all the lines may be filled successively.

ADJUSTABLE MOLD BOARD.—F. C. Millikan, Santa Cruz. This invention is a peculiar construction of scrapers, principally useful as a scraper for leveling off ground which is composed of alternate knolls and hollows, where one part will be too dry and the other too wet to make a crop. It consists in the use of a frame having a scraping mold board which is provided with a mechanism which is rendered easily adjustable so as to stand at any angle and scrape deep or shallow, or discharge its load at will.

Gems and Precious Stones.

[Written for the PRESS by HENRY G. HANES.]

(Continued from last week.)

(7.) **Magnetism.** There are only three elements which attract the magnet, iron, nickel and cobalt, but these metals are contained in so many minerals that the test of magnetism is often a useful one. Some minerals only attract the magnet after being heated. A small magnet will serve nearly all the requirements of the mineralogist, but a delicate magnetic needle is best adapted for minerals possessing this property in a slight degree. The needle should not be strongly magnetized. Every mineral possessing magnetism will attract the north pole and repel the south.

(8.) **Optical properties.** When a ray of light passes obliquely through a transparent substance, its course continues the same as long as the substance has the same density, but should it enter a medium of different density, its course will be changed. This property is called refraction.

Some minerals have the remarkable property of producing double refraction; a line or other distinct object appears double when seen through a crystal possessing this property. This peculiarity was first observed in Iceland spar. Some minerals which refract light doubly, are of such a nature that the double figures cannot be easily observed. The following experiment may be tried in such cases: Make a small orifice in a card, place the card on the side of the crystal most remote from the eye, and observe the light of a distant lamp; the double image will be distinctly seen. Double refraction is not destroyed by the lapidary's cutting.

(9.) **Iridescence.** This appearance of a mineral must not be confounded with the changeable colors of others. The former is named from the rainbow. We have no word in English which exactly expresses the idea conveyed by the French expression, *chatoyement*, which alludes to the peculiar shining colors which appear in the eye of a cat in the dark.

A mineral is said to show changeable or chatoyant colors, when different sets of colors appear or disappear as the position of the specimen is varied.

The colors are said to be iridescent, when they do not change, but have the rainbow colors, being produced by the same natural laws.

(10.) **Color.** Although the color of minerals is sometimes striking and noticeable, yet it is seldom characteristic, the same mineral species often being found of different colors. When it was customary to describe minerals minutely, before they were classified by their chemical character, every possible shade of color was regarded and described, and formed a prominent feature in the descriptions. In Cleaveland's Mineralogy, published in 1816, once a standard work on the science, 77 shades are used in describing minerals, as follows: White, 8 shades; gray, 8; black, 6; blue, 8; green, 14; yellow, 12; red, 14; brown, 7.

(To be Continued.)

A NOVEL AND USEFUL PATENT.—There has been patented through the MINING AND SCIENTIFIC PRESS Patent Agency a device for amalgamating pans and settlers, whereby they can be practically "cleaned up" without ever stopping the machinery. Not only this, but the amalgam is deposited in a safe, and under lock and key and can only be handled by the party authorized. The patentee is Mr. Almarin B. Paul, inventor of the system for reducing and amalgamating gold and silver ores known as "Paul's dry process." We shall shortly describe this new device in detail.

A. W. LAUGHLIN, of the Denver Farmer, and A. W. Merrick, of the News, have started for the Black Hills with a printing press, type and all the paraphernalia of a newspaper office, and will establish the first paper in that region, at Custer City or Hill City, with the name of the *Black Hills Pioneer*.

C. Schindl, of Mokelumne Hill, picked up a piece of gold worth \$40 in his lot, a few days ago, the nugget having been unearthed by the action of the water obtained by bailing out his well.

TWENTY-THREE sacks of Gladiator ore from Boulder, Colorado, was recently sold in Golden at the rate of \$4,000 a ton, the highest price paid for samples of the lot being \$8,000 per ton.

New and powerful pumping machinery, of the same patterns as that ordered for the Savage and Gould & Curry, has been ordered for the Hale & Norcross mine also.

General News Items.

THE Bank of the State of New York has suspended.

JAPAN has formally declared war against Corea.

A TUNNEL through Russian hill in this city is proposed.

THEY are having a printers' strike in New York.

MRS. BELKNAP is to be subpened by the House committee.

THEY are having severe rainstorms in England and Scotland.

THE snow blockade still interferes with travel on the overland road.

DR. PARDEE was elected Mayor of Oakland at the election this week.

THE Wall street king, Daniel Drew, has gone into voluntary bankruptcy.

THEY had a very destructive gale on the English and French coasts this week.

JUNIOR TART, the new Secretary of War, has assumed the duties of his office.

CAPT. W. N. DEHAVEN, editor of the Chico Enterprise, died on the 11th inst.

THE Senate Committee reported against the passage of the Archer fare and freight bill.

THE Consolidated Virginia mine is turning out bullion to the amount of \$100,000 per day.

SILVER is in demand in London, the supply being limited. Bars are very firm, at 53½ pence per ounce.

THE treaties between the Argentine republic and Brazil have been ratified and all difficulties now terminated.

IT is officially announced that the German squadron in Chinese waters will be considerably reinforced for the suppression of piracy.

AN association entitled the Sportsman's Club of California, having for its object the protection of game and fish, has been established in this city.

A MAJORITY in the House Committee on Indian Affairs agreed to report a bill transferring the Indian Bureau to the control of the War Department. The minority will protest.

THE Pacific Mail steamship company has issued a circular by which it is shown that the earnings of the company for the past year amount to \$11,950,000.

THE jetty system of improving the mouth of the Mississippi river seems to be successful, vessels drawing 19½ feet of water having gone to sea through the jetties at Southwest pass.

IN regard to the shower of flesh in Kentucky, Prof. Smith, the scientist, says, in his analysis of specimens examined by him: "In my mind, this matter gives every indication of being the dried spawn of batrachian reptiles, doubtless that of the frog. They have been transported from ponds and swampy grounds by currents of wind, and have ultimately fallen on the spot where they were found."

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

POTOMAC M. CO.—March 12th. Location: Nevada. Capital stock, \$11,200,000, in 112,000 shares of \$100 each. Directors—A. J. Ralston, Jos. Marks, Russell J. Wilson, John Crockett and S. B. Smith.

CHOLAN M. CO.—March 12th. Location: Nevada. Capital stock, \$11,200,000, in 112,000 shares of \$100 each. Directors—A. J. Ralston, Jos. Marks, Russell J. Wilson, John Crockett and S. B. Smith.

MINOR M. G. & S. M. CO.—March 14th. Location: Gold Hill. Capital stock, \$5,000,000. Directors—John D. Jennings, Albert Heath, F. Adams, A. C. Hammond and H. E. McKinney.

TABOR M. M. CO.—March 14th. Location: Storey county, Nev. Capital stock, \$10,000,000. Directors—George Benson, Nathan Atkinson, Martin Jones, J. E. Jewell and J. F. Neesmith.

WESTERN MANUFACTURING CO.—March 14th. Capital stock, \$1,000,000. Object: To do a general manufacturing business, to manufacture and deal in all kinds of goods and merchandise, to buy and erect factories, etc.

Directors—H. R. Mann, D. L. McDonald, Saml. Sachs, A. D. Carpenter and C. R. Greathouse.

Meetings and Elections.

WEST POINT G. & S. M. CO., Gold Hill, March 14th. Trustees—J. J. Holmes (President), T. J. L. Smiley, R. H. Rogers, G. R. Varon and H. H. Flagg. David A. Jennings was re-elected Secretary.

PIONEER M. CO., March 13th. Trustees—J. C. Fall (Superintendent), F. H. Crater, R. E. Brewster, G. G. Berry (President), R. E. Brown (Secretary).

CONS. ALABAMA M. CO., March 14th. Trustees—M. McDonnell (President), J. H. Lovejoy (Secretary), J. L. Trask, R. L. Tracy, F. Mudge, E. A. Edwards.

To Mining Companies.

A Mining and Civil Engineer of long experience, well acquainted with the superintendence of mines and mills, the projecting and construction of hydraulic works, machinery, etc., is open for re-engagement. Apply to Messrs. Dewey & Co., of the MINING AND SCIENTIFIC PRESS, 224 Sansome street, San Francisco, for reference, or to J. B., Postoffice Box 683, Oakland, Cal.

VOLUMES of testimony in favor of HALE'S HONEY OF HORSERADISH and TAB, as a specific for throat and lung diseases, are pouring in from all parts of the country. Pike's Toothache Drops cure in one minute.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Managers, Seal Ponds and Skating Rink.

IN remitting cash to this office, do not send us checks on interior banks, as we generally have to return them by express for collection.

The Golden Sun Gold Mining Company.

Location of principal place of business, San Francisco, California. Location of works, Forks of Route Minn.

Notice is hereby given, that at a meeting of the Board of Directors, held on the first day of March, 1876, an assessment (No. 1) of 25 cents per share was levied upon the assessable portion of the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, No. 702 Market street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the fourth day of April, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 24th day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

WM. SMALL, Secretary.
Office, 702 Market street, Room No. 2, San Francisco, California.

Josephine Gravel Mining Company—
Principal place of business, San Francisco, Cal. Location of works, Brushy Canyon, Placer county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-third day of February, 1876, an assessment (No. 1) of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold and silver coin, to the Secretary, at the office of the company, 331 California street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1876, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the tenth day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

WM. SMALL, Secretary.
Office, No. 331 California street, San Francisco, Cal.

Klamath Quartz Mining Company—
Location of principal place of business, San Francisco, Cal. Location of works, Liberty township, Siskiyou county, Cal.

Notice is hereby given, that at a meeting of the

1876, an assessment of three dollars (\$3) per share was levied upon the capital stock of the corporation payable

Immediately in United States gold coin, to the Secretary, at the office of the company, room 8, No. 11

Mariposa Land and Mining Company of California. Location of principal place of business, San Francisco, Cal. Location of works, Mariposa county, Cal.

Notice is hereby given that at a meeting of the Board of Directors held on the twenty-third day of February, 1876, a assessment, (No. 4) of one dollar per share was levied on the capital stock of the corporation, payable immediately in United States gold or silver coin, at the office of the company, room 33, Nevada block, No. 09 Montgomery street, San Francisco, Cal, or to the Assistant Secretary, at the office, No. 9 Nassau street, New York City.

Any stock upon which this assessment shall remain unpaid on the twenty-fourth day of March, 1876, will be de-

inquent, and advertised for sale at public auction, and unless payment is made before will be sold on Monday the

On the 14th day of April, 1876, to pay the delinquent assessment together with costs of advertising and expenses of sale.

By order of the Board of Directors.

W. H. SANDER LEAVITT, Secretary.

Office, room 33, Nevada block, No. 309 Montgomery street on Francisco, Cal.

New England Tunnel and Smelting Company—Location of principal place of business, San Francisco, Cal. Location of works, Talara County, Peru.

Resolved, That a meeting of the Board of Directors, held on the fifteenth day of February, 1876, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin to the Secretary, at the office of the company.

Any stock upon which this assessment shall remain unpaid on Saturday, the twenty-fifth day of March, 1876, shall be sold, and the proceeds of the sale shall be applied to such assessment; and unless payment is made before, will be sold on Tuesday, the fourth day of April, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

OLINTON O. TRIPP, Secretary.

Office, room 10, No. 401 California street, San Francisco

Qal.

The California Watch Company—Loca-

tion of principal place of business, San Francisco, Cal.
Location of works, Berkeley, Alameda county, Cal.
Notice is hereby given that at a meeting of the Board of Directors, held on the eighth day of March, 1876, an assessment (No. 1) of five dollars per share was levied upon the capital stock of the corporation, payable immediately to the United States gold coin, to the Secretary at the office of the company, room 10, No. 120 Street street, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid on the eighth day of April, 1876, will be delinquent and advertised for sale at public auction, said unless payment is made before, will be sold on Monday, the first day of May, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.
H. T. GRAVES, Secretary.
Office, room 10, No. 120 Street street, San Francisco, Cal.

Third. Open every evening with Mrs. Anna's Dramatic Company. Box office open from 3 p. m. to 10 p. m. Doors open at half past seven. Commence at eight o'clock. Monday evening, March 33, 1876, JOSEPH MURPHY in "HELP."

CALIFORNIA THEATER, Bush Street, above Kearney. Open every evening with the best Dramatic Company in the United States. Box office open from 3 p. m. to 10 p. m. Doors open at half past seven. Commence at eight o'clock. Monday, March 27, 1876, JOHN MC OULLOUGH.

ANGEL'S CHARCOAL DENTAL SOAP for Whitening and Preserving the Teeth. J. W. ANGELL, Prop., San Francisco.

Tuscarora District.

The following letter, describing a new mining district in Nevada called Tuscarora, appeared in a recent number of the Gold Hill News. This town is situated about 50 miles north of Elko, at the foot of the Tuscarora mountains, which form the western boundary of Independence valley, through which the South fork of the Owyhee river takes its course into the Soake, and thence into the Columbia. The district is about 10 years old, but has been prospected very little, having been worked for its placers ever since its discovery, by Chinamen, with very good success, gold being found in all gulches on the range, and in many places a prospect as high as 50 cents to the pan has been obtained, although the ground as a general thing will not pay white men. There are at present about 60 white men in the camp and about the same number of Chinamen. The town consists of about 20 houses, two hotels, two stores, one lodging house, one blacksmith shop, one barber shop, one butcher shop and three or four saloons. Msals can be had for 50 cents and good beds for one dollar per night, although the accommodations are limited, and if there is a rush here in the spring some parties will have to camp out and rough it. It is a very poor place for men to come to in search of employment, there being too many here at present for what work there is to be done; but if a man wants to prospect this is as good a place as any in the State. There are two stage-leaving Elko for Cornucopia and this town three times a week. The fare is \$10 to either place. The ledges here are small, being from 18 inches to six feet in width, and run in a northerly and southerly direction. The country formation is granite, and the ore is easily milled. So far as I can learn, no base ore has been found in the district. Timber is scarce in the neighborhood, wood being worth \$15 per cord, and in consequence every one burns sagebrush.

The principal mine here, that in which the most work has been done, is the Young America. There are at present employed in the mine six men. The company have taken out about 400 tons of ore this winter, which will average about \$100 per ton. They intend erecting a 10 stamp mill as soon as the roads will admit of their hauling the necessary lumber and machinery.

The Oroide mine was found last July, by Col. W. R. DeFreese. He is working six men, and is taking out about three tons of good ore per day. The Colonel has purchased a small mill, formerly owned by the Young America company, and is hauling his ore to it for reduction.

The Grand Deposit mine was found last August by Thomas B. Hanoum. The ledge is about three feet wide, the ore strongly resembling the Comstock. It assays from \$60 to \$800 per ton; it is at present bonded by J. D. Andrews.

The Adeline mine shows some of the richest ore in the district. The ledge is about three feet in width, fine gold being visible in the ore. The South extension of the Young America is down about 80 feet, and has a good ledge. The Northern B ledge has a shaft down about 60 feet, with very good ore indications.

There are many other locations equally as good as the above mines, which I have not yet visited. They will all be worked as soon as the snow melts so that men can work to advantage.

As no prospecting was done to amount to anything before last summer, many think that the best locations are yet to be made. Taking everything into consideration, there is at least a strong promise that this will be a good camp this coming summer, and when the erection of the necessary mills and machinery for crushing the ore is completed it will prove the equal, if not the superior, of its neighbor, Cornucopia; and as its mines are opused and new ones found it will give employment to hundreds of men, and prove conclusively that Eastern Nevada, as a bullion-producing region, is far from yet being exhausted. Not much prospecting can be done in the mountains before April.

From parties who have recently visited the placer mines at Fort Lane the Jacksonville Sentinel learns that the previous reports of their richness are not exaggerated. A nugget weighing \$400 was picked up by Mr. James McDonough, and several other smaller pieces have also been found. The depth of bedrock is not more than two feet, and after sluicing off the dirt gold in considerable quantities is picked up from the bare rock.

The Virginia Enterprise says that there are now more workmen in that city than can find employment. It says: Let no more workmen in any place be persuaded into coming here. But a certain number of men can be worked in the mines along the Comstock lode and in the towns thereof, and many more are now here than are required.

The Truckee Republican of the 1st says: "A new contract has been entered into by the railroad company for 40,000 cords of wood, to be delivered at the track, between the Summit and Verdi. This will put \$60,000 in circulation here, and furnish employment to a great many men and teams."

ALL of the country for four or five miles west of Steamboat springs has been located for cinabar. The Hot springs ground has been taken up, and notices have been posted all over it.

Giant Powder.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1,

For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2,

For medium and seamy Rock, Lime, Marble, Sulphur, Coal, Pipe Clay and Gravel Bank Blasting, Wood, etc.

Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time required for black powder.

The only Blasting Powder used in Europe and the Eastern States.

Sole Proprietor and Manufacturer of the

Celebrated Hudson Force Pumps, Atwood

& Bodwell Windmill Brass Pumps,

Smith's Copper-Lined Pumps,

Plumbers' Force Pumps.

Special attention paid to Brewers', Distillers', Beer and Hot Liquor Pumps, and Wine Pumps. Particular attention paid to AIR PUMPS, also to

DIVERS' SUBMARINE PUMPS.

Artesian Well Pumps Made to Order.

Brass Castings Made to Order.

No. 222 FREMONT STREET, - - SAN FRANCISCO

The Phelps' Manufacturing Co.,

MANUFACTURERS

OF ALL KINDS OF CAR WORK,

Machine Bolts, Bridge Bolts and Ship or

Band Bolts.

13, 15 and 17 Drumm Street, San Francisco. 4v241y

Miners' Foundry and Machine Works,

CO-OPERATIVE,

First Street, bet. Howard and Folsom, San Francisco.

Machinery and Castings of all kinds.

SHEET IRON PIPE.

THE

Risdon Iron and Locomotive Works

Corner Howard and Beale Streets,

Are prepared to make SHEET IRON AND ASPHALTUM PIPE, of any size and for any pressure, and contract to lay the same where wanted, guaranteeing a perfect working pipe with the least amount of material.

Standard sizes of railroad Car Wheels, with special patterns for Mining Cars. These small wheels are made of the best Car Wheel Iron, properly chilled, and can be fitted up with the improved axle and box—introduced by this company, and guaranteed to outlast any other wheels made in this State.

All kinds of Machinery made and repaired.

2v22-3m JOSEPH MOORE, Superintendent.

Empire Foundry,

Nos. 137, 139 and 141 FREMONT STREET, SAN FRANCISCO

RICHARD SAVAGE, Proprietor.

Heavy and light Castings of every description. House Fronts, Milling and General Machinery estimated and constructed at shortest notice. On hand the celebrated Occident and French Ranges, Burial Caskets, Grates and Fenders, Road-Scrapers, Hydrants, Tugger Irons, Ploughwork, Sash Weights, Ventilators, Dumb Bells, Gipsies, Ship Castings, SOIL PIPE of all sizes, Fittings and Cauldron Kettles in stock at Eastern rates. SHOES and DIES a specialty. Ornamental Fences in large variety. 4v30-1yr.

CALIFORNIA BRASS FOUNDRY,

No. 125 First Street, opposite Minna,
SAN FRANCISCO, CAL.

All kinds of Brass, Composition, Zinc, and Babbitt Metal Castings, Brass Ship Work of all kinds, Spikes, Sheathing Nail, Rudder Braces, Hinges, Ship and Steam Boat Bells, and Gong of superior tone. All kinds of Cocks and Valves, Hydraulic Pipes and Nozzles, and Hose Couplings and connections of all sizes and patterns, furnished with dispatch. J. H. WEED, V. KINOWELL.

THOMPSON BROTHERS,

EUREKA FOUNDRY,

129 and 131 Beale street, between Mission and Howard,
San Francisco.

LIGHT AND HEAVY CASTINGS,

of every description, manufactured 2v16fo

STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 60-Horse power. Also, Quartz Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron Tanks, etc. For sale at the lowest prices by 1v27tf J. HENDY, No. 32 Fremont Str. et.

MECHANICS' INSTITUTE
SAN FRANCISCO

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

PREMIUM
AWARDED TO
W. C. WILCOX & CO.
FOR BEST
STEAM PUMPS.
Wilcox's Patent.
1875.

AFTER ONE OF THE
MOST THOROUGH TRIALS

Ever Had in the United States,
BETWEEN COMPETITORS
—OF—

Best Established Reputation,
In which, at great expense, the different Steam
Pumps were tried under every test known
to experts, the Examining Committee
of the Tenth Industrial Fair of the
Mechanics' Institute have
awarded to us their

GOLD MEDAL
—FOR—
Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER
CONTRACT, guaranteeing their ability to
perform any specific work for which
steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

**FEEDING BOILERS, RAISING WATER
FROM WELLS; STEAMER AND
SHIP PUMPS, ETC.**

We would also call the attention of those
interested, to our Direct Acting Deep-Well
Pumps for raising water from

Any Desired Depth.

Also our Especial Construction of Pumps
FOR HANDLING QUICKSILVER or heavy
liquids.

We claim that our Pumps are the **best** ever made in **simplicity** of construction, economical use of power, **durability** and perfect adaptability for general uses, and we
ask all persons interested to investigate **our title to this claim.** Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

LATEST IMPROVED
HENDY & COCHRANE'S ORE-FEEDER,
FOR QUARTZ MILLS.

It is confidently believed to be the ne plus ultra of ore-feeders. One of these machines, on exhibition at the
late Mechanics' fair, received the premium over all competing feeders. One was recently set up at Schnabel's
mill in Newcastle, Placer county, Cal. It very soon showed itself to be the thing wanted; all other feeders
under examination were at once rejected, and three more ordered for the same mill. We refer to the following
mills using the Cochrane feeders: St. Patrick, Pugh, Green, and Julian, Newcastle, Placer county. Keystone
Con. M. Co., Lincoln and Onda's mill, Sutter Creek, Amador county. Tybo Con. M. Co., Nev.
For description send for circular. **J. HENDY, 32 Fremont Street, San Francisco, Cal.**
where it can be seen in operation. Also, manufacturer of Hendy's Improved Amalgamator and Concentrator
and dealer in Quartz Mill Machinery and Machinists' Tools.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:
"We started the heavy 20-inch Corn Mill last Friday you
sent to Baldwin & Tabor, Manchester, N. H. We ran it most
all day, and ground 60 bushels corn per hour. The mill you
sent us at Haverhill, Mass., for A. S. Hook, is doing wonder-
fully. It is grinding on an average 2,500 lbs. good meal per
hour, and has ground 2,800 lbs. in an hour. It is driven by an
engine with a 9-in. cylinder, and takes the place of a 30-in.
mill of another kind that, when doing its best and loading
the engine with all it could carry, only ground 1,500 lbs. per
hour. If there is a mill built that can beat that we would be
pleased to see it brought out."

San Francisco,
Are the only Agents for sale of these
Engines in the Pacific States.

Hoisting Engines. Mining Engines.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been too long in use on the Pacific coast to require any special recommendation from us. They are well known from Alaska to Mexico. We would refer with confidence to any one of the hundreds in use. They still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship to compete with cheaper engines. They have lately been greatly improved by adding large drums, and reverse motions.

MINING HOISTING ENGINES.

(Manufactured by the same parties.)
Our new Mining Engine is built from plans and specifications of several of our most successful MINING ENGINEERS, and the result is the most complete

Double Drum Hoisting Engine
Ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. These engines may be seen in use in Ophir, Con. Virginia, Chollar, Europa, Niagara, Leviathan, Phil Sheridan, and several other mines on the Comstock Lode. For sale only at

SAN FRANCISCO, SATURDAY, MARCH 25, 1876.

VOLUME XXII
Number 13.

The Glacial Epoch.

The impression which generally obtains in regard to the glacial epoch is that it consisted of an enormously long and unbroken period of cold, during which the northern hemisphere of the earth was covered with an immense ice cap of many miles in thickness within the Arctic circle, and gradually thinning out to nothing as it approached the tropic. This indeed was, at first, regarded as a fact by all scientists. But, as observations multiplied the interpretations of the deposits failed, in many instances, to sustain such a theory.

Deposits containing organic remains of tropical and temperate fauna and flora were found placed between immense deposits of unmistakable glacial origin. Remains of the elephant, the rhinoceros, the hyena, and of the tropical plants which always accompany those animals, were found in heavy strata, which rested directly upon other deposits which must at some time have been covered for a long period with an ice sheet; and these animal remains were again found covered with other glacial deposits of a later period. Such reports were at first ignored as too uncertain to be received as facts, or other and local causes were assigned for such peculiar superposition; but the accumulation of evidence finally led to a division of the glacial epoch into three parts—the second being a long period of interglacial warmth, during which Greenland and the northern portions of America and Europe were subjected to a semi-tropical climate.

But as observations have been extended, geologists have been compelled to further modify their theories and admit of still further divisions of the glacial epoch. The evidence now points to quite a number of changes between the extremes of heat and cold. These evidences have been found in numerous instances of well marked river terraces in Switzerland, Scotland and other portions of Europe, and also in the Lake Champlain and St. Lawrence river valleys in this country. In addition to the surface indications numerous borings have also been made at a distance inland from the terrace fronts, which fully sustain the multiple theory.

The first to detect the significance of these peculiar intercalations was the eminent Swiss geologist, M. Marlot, who some 20 years ago announced the existence of a warm interval intercalated between two glacial periods. The times of the continuance of these periods have also been made a subject of study by Professors Heer and Leibig, the first of whom placed the time required to deposit a certain peat bog at 6,000 years, while Leibig assigned 10,000 years for the same purpose. As this peat bog was about 60 feet thick and contained large quantities of the remains of elephants, stags, cave bears and other temperate or semi-tropical animals, besides insects, it is quite certain that the ice age must have been broken for a long time to admit of such an intercalated deposit.

These evidences add still further to the vast accumulation of proof that the earth must have been inhabited by the higher order of animals for an almost indefinite length of time. The fact is also now placed quite beyond the region of doubt that man existed on the earth anterior to the time of the last glacial period, the continuance of which cannot be set at less than 10,000 years, while a much greater duration must be allowed to the present era of warmth, during which man has been a constant occupant of the temperate zone.

It has been assumed, and with a great degree of probability, that these irregularities of seasons may be attributed to the gradual change of the inclination of the earth's axis—that the earth is constantly vibrating in its inclination, from and to a perpendicular to the plane of the ecliptic—that on an approach to the perpendicular the tropics are extended north, while with its retrocession therefrom the frigid zone is brought down to near the tropics and we have a glacial period, which continues until by another approach to a perpendicular the ice is melted preparatory to another period of warmth. If this assumption is correct, a record must be inevitably made upon the earth's crust, and it is now

the province of the geologist to determine how many times the earth has thus swung back and forth since its crust became sufficiently solidified to keep the record, and to calculate, approximately, the periods of time thus occupied.

It is now well known that the ancient Egyptians and Chaldeans made astronomy a matter of very close study, and that they mapped the heavens so far as visible to the naked eye. It has also been pretty well ascertained that the pyramids had more or less connection with the astronomical studies of the Egyptians. The great pyramid stands with its four sides exactly facing the four points of the compass. It has also been observed that a line of its masonry points very nearly in a line to the North star, near, but not exactly to which the North pole of the earth also points. May it not be that the changes of the seasons of the earth to which we have alluded, were also known to that ancient and mysterious people, and that they also were curious to learn the cause? They knew nothing of a "North pole;" their theory was that the earth and the North star were fixed and immovable; that the sun in its revolutions around the earth came further north in summer than in winter. May they not also have

Saw Filing.

The accompanying engraving represents a saw file guide recently patented, for guiding the file during the operation of filing saw teeth, and is done in such a manner that exactly the same bevel and pitch shall be imparted to each tooth, and the file is made to cut more smooth and even; and which also admits, on the saw being refilled, of forming the teeth with the same bevel and pitch as in the beginning, thus requiring much less filing, with less wear to either the file or the saw, and the operation of filing is greatly simplified. The saw is secured in a wooden clamp, as shown, and held in a vice. The clamp has grooves on each side which extend its entire length, these serving as guides for flanges on the legs at the lower part of the frame, A. The frame may be freely moved along the grooves, and is by them maintained in uniform position as regards the saw. The sliding frame holds a graduated circle, B, and is held by a set screw, C; the guide rod, D, passes through holes in the circle as shown.

ROTH'S SAW FILE GUIDE.

suspected that the inclination of the earth might have a slow movement to and from the average position of the sun? Admitting these suppositions, what more natural inference than that a gradual increase of that inclination would produce the great season of cold, the existence of which might have been handed down from primeval races which had been driven from their warm and pleasant northern homes thousands of years before, to seek more southern latitudes as the earth gradually inclined itself away from the sun? Perhaps these same Egyptians might have been the descendants of those people. Admitting these further suppositions, would not such an intelligent and enquiring people have endeavored to devise some plan to detect and keep a record of the progress of such an important change? What more feasible way of doing so than to have fixed a permanent line, pointing to the only fixed star in the heavens, so that its possible deviations might be watched from generation to generation? That line, which has now maintained its position for 4,000 years, varies in pointing out the North star just about as much as the North pole varies therefrom! Have we here data from which to calculate the quantity of the enormous periods, whose effects are now so surely read by the geological student? Have we thus connected the observations of the ancient Egyptian astronomers with those of our own day? Another period of 4,000 years will be required to prove or disprove this assumption; but we need not erect a costly pyramid or even keep watch over that already erected to hand down our observations to the astronomers of A. D. 5876. The printing press will surely preserve our records, and the improved instruments of to-day will serve our astronomers far more accurately than did the skillful architects of 4,000 years ago.

It will seem that the latter can be adjusted so that any mark on its periphery coincides with a fixed mark on the frame, and thus the file, which is connected with the guide rod, may be set so as to impart any desired bevel to the teeth, this being denoted by the graduations on the circle. The file is supported in the arms attached to the guide rod, its end being inserted in a hole in one, and a screw clamp holding it to the other; by loosening the screw, the file may be turned so as to give any desired pitch to the saw teeth. At E is an indicator which shows the pitch at which the file is set, and thus allows of easy resetting to the same inclination at any future time, as when using a new file or another corner of the same file. The guide has in connection with it a table, in which are shown and arranged bevels and pitches for each kind of saw, and for sawing the various kinds of wood. This arrangement makes the guide so easily set for either kind of saw, that those not experienced in the art of saw filing find no difficulty to obtain proper bevels or pitches. The guides are made in a very neat and substantial manner, will last a lifetime, and are sold at so low a price as to place them in the hands of every one using a saw. By the use of this guide each person who uses a saw will be enabled to file his own saw in such a manner that it will do its own work in the very best manner, cut smooth, fast, straight and easy. These implements are manufactured by E. Roth & Brother, New Oxford, Adams county, Penn., and they inform us that a single one will be sent to any part of the United States for \$2.50. The guide is applicable to circular as well as straight saws.

The employees of the Richmond mine, at Eureka, have refused to accept trade dollars in payment of wages.

California and the Centennial.

With all the enthusiasm which has been manifested towards the Centennial exhibition in honor of the nation's birthday, we must confess that very little of it has appeared in California. Although individuals in different parts of the State have proposed to contribute articles of interest, no general movement has been made, nor has any appropriation been made by the State itself. The only large general collection of articles showing California products and curiosities which has been arranged, is that forwarded by the Central Pacific railroad company in care of an agent of their own.

There is no building for Californians to meet in, nor is there any official duty authorized to receive articles sent from this State. The Society of California Pioneers have appointed a committee to take the matter in charge and solicit funds to erect a Pacific coast Centennial hall at Philadelphia.

Although these gentlemen have found some difficulty in their work, they are now confident of success. The State of Nevada has appropriated \$1,000 towards the object, and Oregon and Washington will assist. The San Francisco delegation of the Legislature have been importuned to push the matter of the appropriation through as rapidly as possible. A bill is already before the House appropriating \$25,000 for Centennial purposes, but its passage has been very much delayed. If the bill is not passed very soon it will be too late for California as a State to make any proper showing. About \$5,000 of this will probably go towards the Centennial Hall.

The purpose primarily in view in erecting the Pacific Coast Centennial hall, is to provide a place of resort and shelter for the people of the Pacific coast visiting the exhibition, and at the same time to make the building, as far as practicable, a Western coast feature, by displaying in its interior finish a variety of characteristic woods and the addition of other objects of interest as means at hand will permit. Although inaugurated under the auspices of the Pioneer society, it is not intended to limit the interest and sphere of the scheme to its members alone. The opportunity to participate in the enterprise is thrown open to the Pacific States and Territories, and the special assistance of societies, corporations, orders and individuals is particularly requested and desired, as the object in view is common to all the citizens of the Pacific border. The committee having the matter in charge consists of Wm. S. O'Brien, (President), Josiah Belden, John B. Frisbie, Peter D. An, A. C. Bradford, F. MacCrellish, Louis Sloss and Albert Williams, (Secretary). The necessary funds are to be secured, aside from any appropriations which may be made, by the sale of tickets at \$5, each admitting the holder and his friends to the free privileges of the hall. These tickets will be given to subscribers according to the amount subscribed. Those desiring to aid this worthy object can address the Secretary of the committee, Albert Williams, 507 Montgomery street, in this city. We hope a liberal sum will be forthcoming.

It is a matter of regret to all old Californians that our young but wealthy State should stand a chance of being poorly represented when it has so much to show. The people should respond heartily in accordance with their means, to aid in the display of the products of the State. We urge all who are able to do anything to further the object to do it quickly, so that California will be properly represented at the great gathering of the peoples of the earth.

The branch "put" and "call" enterprise of McKee & Co., at Virginia City, has not been as successful as was anticipated by its projectors. The agent acknowledges that the Comstock miners know too much to be profitable customers. The receipts of the Virginia office foot up \$13,000, while the disbursements amount to \$60,000.

According to the books of the Union Pacific a daily average of 50 emigrants for the Black Hills go over that road.

The Virginia and Truckee railroad is now running 24 trains daily between Virginia and Carson.

Heat and Mechanical Force.

EDITORS PRESS:—Will some of your readers who are familiar with the subject and possessed of practical knowledge oblige others of your subscribers by giving us some information on the following points:

It is stated as Soule's equivalent, that a unit of heat (the amount of heat which will raise the temperature of one pound of water one degree) is equal to the mechanical force that will raise one pound 772 feet high. Now, how do they ascertain this result?

A pound of carbon is said to give out in burning 14,500 units of heat (we are dealing in round numbers), and as about 1,000 units of heat is required to evaporate one pound of water, and therefore one pound of carbon would evaporate say 14½ pounds of water, now, how much power would the above amount of water, converted into steam at a pressure of three atmospheres, give when applied to an ordinary non-condensing steam engine, making, we will suppose, no loss in friction or condensation? Also, now under this statement, how high would a unit of heat lift a pound weight? Please answer and oblige. OBSERVER.

The Contract System of Mining.

A correspondent of the *Eureka Sentinel*, writing from Ruby hill, among other things says: From reports in circulation on Ruby hill I infer that the Richmond mining company has already let, or are making arrangements to let, the whole Richmond mine on contract. A great deal of the ore now taken from the mine is extracted on contract by the ton, and the company's manager, having found it a convenient way, has concluded to let the entire mine.

There is no doubt that the contract system, if honestly carried out, is an economical way to work mines. When honestly carried out it is open to competition. Tenders are called for in the public press, and the proposal of the lowest responsible bidder is accepted. When this plan is adhered to there is no room for middlemen. The company gets its work done at the lowest rates. The profits from the labor of each individual miner are small, but taken together, where there is a large number of men employed, they aggregate a good sum at the end of the month.

On the other hand, the contract plan when not carried out on the square is the worst system that can be introduced—the worst for the company adopting it as well as for the miners. It is to-day the cause of many mines in Nevada lying idle, which, if they had been legitimately worked, would be productive. This is especially the case with mines owned by English companies. English capitalists reside at a distance from the scene of operations. Their representatives seldom come on the ground to examine the mines or the means that have been adopted to make them remunerative, and when they do come, sufficient opportunity is not afforded them to make themselves thoroughly acquainted with all the practices of their agents. Their agents are generally appointed in England. They expatriate themselves from their own country in the hope of realizing an independence in a few years. When they come here they set to work with a good will to accomplish the desired object. Many of them bring with them a clique of consorts or followers. All the lucrative offices are bestowed on these followers, and new offices created for their special benefit. They get contracts at far higher figures than would be given to mere strangers. Those who are not in the "ring" find it advantageous to connive at it and hold their tongues. In the presence of the miners, they are "in with the superintendent," and it is the safest way not to interfere with them.

Like our State politicians, these men are very fond of talking about retrenchment and economy. With them, economy means reduction of the wages. If the mine has failed to pay dividends, it is owing to the high price of labor. A show of economy is made by an attempt to lower the wages or increase the hours of labor. A cent is put into the company's pocket with the right hand, while a dollar is taken out with the left.

From the Black Hills.

The *Virginia Chronicle* publishes a letter from a former resident of Virginia, as follows:

CUSTAR CITY, FEB. 26, 1876.—I got in here on the 24th, and am much disappointed in the country. Men are working for three and four dollars per day at building cabins. I went down French creek and prospected but could not get more than two cents to the pan. The gulch is so flat that you cannot tell which way the water runs. I went out with a party of 22. Fourteen of our party have started for Hill city. Hill city is 16 miles from here. Most of the others will start for the back trip to-morrow morning. I will remain in Custar city, but I think it a great humbug. They have got a mill running and another one is on the road, which will be here in a few days. I will stay here, for I have got a good outfit and will take the chances. All the town lots are taken up and they are asking big prices for them. There is no money here. I have not seen a bit of dust. Don't think of coming here.

THE Douglas mill, Lower Gold Hill, has been obliged to shut down for want of wood.

Japanese Gold.

The Native Gold Fields and Methods of Mining and Reduction.

The accounts of the richness of Japan in gold ore have been copied from book to book, without having been sufficiently weighed and tested. When the Portuguese first came in contact with the Japanese—and even still many years later—there was a considerable stock of precious metals, and especially gold, in this country. This relatively large amount of gold does not prove, however, the extreme richness of the country, because it was in reality the product of gold washing during many centuries. Japan being closed at that time to nearly the whole world, the gold remained in the country and augmented with every year. Under such circumstances the quantity of gold must have been considerable after many centuries, even if the country contained but a very moderate quantity of ore. The extreme cheapness of labor in former times allowed of gold washing out of very poor gravel, which could not, without a decided loss, be worked either in Europe or America. The production of gold being moreover larger in relation to silver than in other countries, the relative value of the first precious metal became quite different from our standard. Whilst in Europe the relation between gold and silver varies only a little between 15 to 16.1, there has been a time when this relation was in Japan 6:1. The Portuguese and afterwards the Dutch have had the advantage of leveling the ground considerably, whilst the opening of Japan in latter years has done the rest. The quantity of gold metal exported by the Portuguese during their stay in Japan, 1550–1639, may be estimated at least \$59,500,000 sterling, or an average of 660,000 yearly. Ksempfer speaks even of some years with an export of 2,500,000 of gold, and adds in his peculiar style, (Book iv., chap. v.), "If this trade had lasted but twenty years in the same degree, the Portuguese would have exported (out of this Ophir to Macao) the same quantity of gold and silver which the Bible says there was in Jerusalem during Solomon's time."

The Dutch afterwards exported chiefly copper and silver from Japan, but also gold, especially from 1649–1671. The quantity of silver exported by the Dutch alone during the seventeenth century may be valued at 112,000,000 of taels, and the quantity of gold exported the same period at 6,192,900 pieces of the old *koban*. During the eighteenth and nineteenth centuries there were besides exported considerable quantities of gold and copper. The whole quantity of Japanese gold and silver exported during the sixteenth and seventeenth centuries may be estimated as follows: Portuguese, gold and silver, \$59,500,000; Dutch, gold, \$15,482,250, silver, \$28,000,000,—\$43,482,200; total, nearly \$103,000,000.

We have had the opportunity of seeing many gold ores out of different parts of Japan. The last exhibition in Kyoto (1875) had about 20 samples accurately labeled, with the localities of occurrence of nearly all these provinces, in which gold is more or less worked. By the kindness of the local government we obtained and examined these specimens, together with the samples in former collection. Most samples consisted of ochry silicious conglomerates and ochry argillaceous gravel, there being very few samples of more dense and pure auriferous quartz or feldspar. Nearly all rocks had a disintegrated character, caused by the long-continued action of air and water. The samples of alluvial auriferous gravel proved undoubtedly their origin as products of disintegration from primitive rocks, under the continued action of torrents. The gold in these alluvial deposits was found in very small scales, so that the aid of a lens was necessary to discover them, and in many instances the gold dust could only be ascertained after a process of washing and levigation. Gold in dendritic forms we have only seen in some samples of pure auriferous quartz from Satsuma and Kai. The general aspect of all these ores was poor. Considering further that samples in an exhibition usually represent the better kinds, we cannot but believe that Japanese auriferous gravel or quartz is, as a rule, poor, although these gold-bearing minerals occur, often in considerable quantity, in many different localities.

The Japanese manner of extracting the gold from the auriferous minerals is very simple and agrees in the main points with our old Western method. If the gold, as is mostly the case, is to be extracted from sand or alluvial deposits of rivers and torrents, then the separation of the small gold scales is effected by washing the gold sand either on an inclined plane or levigation apparatus, or directly on mats in a washing dish. The gold dust obtained by the washing process is melted on the bottom of calcinated salt, until a button or half round nugget is obtained. In the gold mines where the auriferous mineral consists of hard quartz rock, feldspar or feldstone, the ore must be crushed by means of large iron hammers. It is then roughly powdered in a mortar, in which the pestle is worked by the foot, and finally ground in a stone mill. Being thus minutely divided, the powder is washed in the same way as above.

When the ores consist of auriferous metallic sulphides, (copper or iron pyrites, grey copper ore, etc.,) they are first crushed and roasted. The roasted mass is powdered and melted until a coarse metal is obtained. The earth now contains the whole of the gold. The crude metal is then fused with some lead, which extracts the gold and falls to the bottom. The

alloy of lead and gold is then finally treated by a cupellation process.

The process of abstracting gold from the ore by means of amalgamation with quicksilver is unknown to the Japanese. The Japanese possess no good process for the separation of gold from silver. Hence, all Japanese gold contains more or less silver.

On the occasion of opening a gold mine, according to old Japanese custom, first a feast, the feast of the mountain gods, must be celebrated at the mountain or place where a gold mine is to be opened. The best and most propitious day for this feast is the 9th of the 7th month. A small temporary shrine is constructed, and wrestlings and other kinds of amusements are ordered from Kioto or Osaka to smuse the villagers and the miners, who will enjoy the opening of a new mine. The priest takes care to ask the favor of the gods for the new enterprise.

When the miners have brought their ore out of their mine, the women commence by crushing it roughly with hammers; subsequently it is powdered in the mortar and stone mill. The powder is now given into the *Nekata*, the water of a bamboo aqueduct running into this reservoir and flowing off, through the opening below, on the wooden plane. The gold-sand runs off with the water, but, being heavier than the small particles of sand and gravel, the gold dust remains in the greater part on the wooden plane, where it is collected and still further washed by the cotton sweeper. The water runs finally into a large hole, where the heavier gold dust which might have escaped from the plane, sinks to the bottom and can be collected afterwards. The gold-sand being thus concentrated, it is transferred to the shallow wooden washing board or the so called "pan." This is done with great care, in a large wooden tub filled with water. The board is first floated on the water, and the sand slightly shaken by a slight oscillating motion. From time to time the board is raised from the water, and the less heavy sand washed away from the gold by some quickly effected longitudinal jerks. Thus alternately and skillfully moving the board, the bright yellow gold grains become more and more visible and separated from the sand or quartz. Finally the gold dust is dried and further separated, by blowing, from some heavy iron sand, which is generally still present. The process of washing on the board requires great skill and dexterity.

The gold thus obtained is now fused and hammered in order to obtain a metal button or bar. A round cavity is made of ten parts of calcinated salt and buck-ashes and one part gold dust put on it. By means of a strong charcoal fire the gold becomes fused, and is then strongly hammered until the piece of metal has the desired shape.

The best gold field in Yesso, tried by Mr. Munroe, was that of Toshibetsu. The gold-sand here contains, however, but one-half of the amount of gold which the poorest gold fields of California contain.—*Japan Mail*.

THE PRODUCTION OF ARSENIC IN COPPER MINES.—In 1873, 5,449 tons of arsenic were produced in England. More than a third of it came from the Devon Great Consols mine. Sometimes 200 tons a month are sold from this mine, a quantity of white arsenic sufficient to destroy the lives of more than 500,000,000 of human beings. The Commissioners of Mines saw stored in warehouses of the mine, ready packed for sale, a quantity of white arsenic probably sufficient to destroy every living animal upon the face of the earth. The Commissioners consider that, in the case of mines in which arsenic is actually manufactured, it is only reasonable that the manufacture of a poison so virulent should be subjected to a special State supervision; and they submit that an officer should be empowered to require that the best practical means be taken not only to prevent the poisoning of the air by the volatilization of the arsenic, but also to hinder the access of the poison to the running water.

THE contract for bridging the Owyhee river has been forwarded, funds having been liberally subscribed for that purpose. The completion of this bridge will insure to Winnemucca a heavy freightage to Cornucopia, and in return will be made a shipping point for all bullion taken from that now fast increasing and popular mining camp. The road from this point exceeds in length by a few miles other roads now in use to Cornucopia, but the admirable grading of the Winnemucca route, and the total absence of snow drifts during winter, will render it the established and acknowledged route.

ANOTHER coal vein has been discovered near Seattle. It is nine feet thick, the outcroppings much resembling those of the Talbot mine, and it is situated near the intersection of the White and Stuck rivers. The vein has been followed for a mile or two. Several of the farmers near by rushed up to Olympia to enter the land, only to find out when they got there that the coal was on the old Mucklehoot reservation, and was not open for entry.

THE Suto tunnel is now in 12,600 feet, and work in the header is progressing at the rate of 100 feet a week, while the tunnel is being widened out at the rate of 400 feet per week. One hundred and ninety men are now employed, and 20 mules.

THE citizens of Independence, Dalles, Jefferson and Buena Vista propose to construct canals and mill races at these points, thus making fine water powers for mills and factories.

Prospecting for Sulphur at Steamboat Springs.

The recent remarkable discoveries of ores and minerals of various kinds made in the neighborhood of Steamboat springs, are causing a considerable amount of speculation in regard to what may underlie that region at no great depth. Some who have been ruminating on the matter are of the opinion that under a crust of 200 or 300 feet in thickness there exists a large lake of boiling water, while others believe that at about the same depth below the surface still is fire and red hot and molten rocks. Those who advance the first mentioned theory say that the minerals contained in the water of the boiling lake first formed a crust around the shores, and that this grew as ice grows upon a pond in winter, till the concretions covered the whole of the water, except spout holes here and there. Through these spout holes steam and water were forced up, and thus thickness was gradually added to the crust covering the subterranean lake. They think that this lake may extend under the greater part of the Truckee meadows, as some years ago, on the occasion of a severe earthquake, all the land both in Steamboat valley and Truckee meadows was rolled and tossed like the waves of the ocean.

Prospecting for Sulphur.

Those who believe that there is fire somewhere far down in the bowels of the earth say that beds of iron pyrites are necessary to produce (by their decomposition) the combustion, and all below must be solid, or at least there is no body of hot water of such an extent that it could be called a lake. They also say that there can be no lake, because in certain places there rush up strong blasts of hot, dry air or gases, which must come from a point where there is fire, or at least great heat, but no water; as no steam is mingled with the gases. In places a mile or two to the westward of the present active springs, where men are now engaged in prospecting for sulphur, it is found that at the depth of three or four feet the rock is quite hot and the sulphur in some of the beds is so hot when first opened upon that it cannot be held in the hand. This great heat at a point so far from the present active springs is what has given the miners the idea that a lake of boiling water underlies the whole region. An experiment that many would like to see tried would be the boring of a hole somewhere in the neighborhood of the present active springs. The rock is somewhat like lava and would be penetrated very rapidly with a diamond drill or even with ordinary steel boring apparatus.

Is There an Underground Chamber?

We are of the opinion that a depth of 200 feet would not be attained before an underground fissure or chamber would be tapped that would throw a stream of water to the height of from 100 to 200 feet, either constantly or at regular intervals. The present proprietor could in no way so cheaply add to the several attractions of the place as by starting a bore there, not for oil, but for—well, that which is supposed to be not far away from that place. It is a sure thing that a hole bored into the red hot bowels of Steamboat springs would develop something worth seeing, and we hope the proprietor will prospect the lower levels of his property during the coming summer. Deep in the earth there is pent up at that place an immense force. In the spring of 1860 there was a sort of well toward the north end of the range of springs that sent a column of water three feet in diameter to the height of at least 60 feet at intervals of about eight hours. This finally became clogged up, and in 1862 a stream of hot water about three inches in diameter was thrown to the height of about 100 feet at intervals of half an hour. The hole from which this stream was thrown soon became clogged up, and since then we have had no extraordinary spouting of water at the springs, but an artesian bore would doubtless start a new geyser.—*Virginia Chronicle*.

ON the summit of Pike's Peak, over 14,000 feet above the sea level, where there is not a trace of any vegetation, or, indeed, any earth upon which shrubs or grass could grow, the mountain rat, an animal twice as large as the Norway rat, abounds in vast numbers, overrunning the United States signal station on the apex of the mountain. Last summer two terriers, which distinguished themselves in the rapids of Chicago and Denver, were taken to the house and turned loose at night into the kitchen, but in the morning one was missing entirely, and only the skeleton of the other remained, both having been overpowered by superior numbers. Four huge cats have now been introduced, and it is expected that the number of rodents will soon be visibly diminished.

BESIDES their 120-foot plank, the Oregonians have made up their minds to exhibit at the Centennial a section of a fir tree 7 feet 6 inches in diameter 130 feet from the ground, and the section of another fir 5 feet through 200 feet from the ground. Oregon will not have any palm tree at the exhibition, but she is sure to carry the palm away so far as trees are concerned.

THE Oakland, Berkeley and Contra Costa railroad company promises to build the entire road from Walnut creek, Contra Costa county, within 18 months, expending \$1,000,000 in its construction. The company will also establish a ferry from the foot of Market street, with boats equal to those of the Central Pacific railroad company.

SCIENTIFIC PROGRESS.

New Industrial Applications of Salicylic Acid.

M. R. Wagner, in the *Technologist*, enumerates a large number of industrial uses to which the newly discovered salicylic acid can be applied in addition to its various medicinal uses. If during the past two years science had made no other discovery than this useful product, it would still have conferred a most important boon upon mankind. We enumerate, briefly, some of those numerous applications:

The Preservation of Food Products.

The antiseptic, tasteless and innocuous qualities of this acid render it of great value in this direction.

Fresh, uncooked meats, washed in an aqueous solution of salicylic acid and afterwards secured in hermetically sealed cans, and placed in a cellar, was kept, by Mr. Wagner, perfectly free from taint from April 28th, 1875, to June 25th.

When added to salt brines used for the preservation of food, it is found a great assistant and keeps the brine sweet.

It has been used with great benefit in the preparation of smoked meats.

One or two parts in one thousand kneaded into fresh butter will keep that article sweet in summer time from four to eight times as long as when nothing but salt is employed.

Its Use in Arts and Manufactures.

In the manufacture of wine it is thought (though not yet tried) that a very small quantity placed in each cask will so retard and modify the progress of fermentation as to be of great use in securing and preserving the delicate bouquet of that product. If so, its aid will also be valuable in the manufacture of vinegar.

In the manufacture of glue and gelatin, salicylic acid may be advantageously employed in the macerating vats, also in boiling it appears to facilitate the conversion of the tissues into gelatin.

The sizing used by weavers and the paste employed by bookbinders, paper-box makers, etc., is preserved from fermentation by this new and useful product.

The albumen of blood or eggs may be preserved by it for an indefinite length of time.

In tanning salicylic acid seems to promise a new and most important agent. Its presence in the "sour bath" prevents putrid exhalations and gives to the hide a decidedly improved appearance. It is also thought that it will facilitate the ordinary action of tanning materials in its action upon the gelatin and in preventing souring of the bark liquors, which produces gallic acid that works a hindrance to the tanning process.

Its employment is specially advantageous in the preparation of skins for gloves, and in the preparation of parchment, vellum, gold-beater's skins, strings for musical instruments, etc.

It has also been found of great advantage in the preparation of dyes, inks, perfumery, etc.

The full value of this most important product is still far from being fully known. Mr. Wagner and other scientific investigators are continuing their researches, and will no doubt continue for a long time to come to announce further applications of this acid in chemical arts and in manufactures.

Geographical Progress in 1875.

In his late annual address, in New York, before the American Geographical Society, Chief Justice Daly presented a comprehensive statement of the "Explorations, discoveries and geographical work of the world in 1875" of which the following is a brief summary:

The year has been distinguished by activity in every branch of scientific enquiry, but particularly in geographical exploration and discovery. No single year's work since the 15th century has exceeded it in interest.

In the United States the work of exploration has been confined largely to the coast survey, in which the work of Mr. Wm. H. Dall, on the northwestern coast, occupies a decided prominence. Lieut. Wheeler's explorations in Colorado and New Mexico have also been important and exceedingly interesting. The ruins of ancient villages in those regions show that that region was once as densely populated as the Eastern or Middle States now are—the number of buildings to the square mile being equal if not greater. Some of the ruins in New Mexico were fortified structures having as many as 500 rooms each! The ruins of towns were found regularly laid out in streets and squares. Many important mineral developments have resulted from the explorations in Colorado.

The important Arctic event of the year has been the dispatch of an expedition of the British government under the command of Capt. Nares. Several other expeditions have also been sent out in the same direction by the Swedish and Russian governments.

Much has also been done during the year in Asia. The explorations in Northern Asia have induced the Russian government to decide definitely upon the construction of a railroad through that region to the shores of the

Pacific. Important explorations have also been pushed in India, during which a male and female specimen of a dwarfish race have been captured, who are of a race of which no trace had ever before been found.

The man was four feet six inches high and 26 1/4 inches about the chest. He had a round head, with coarse, black, woolly hair and dark brown skin. The lower part of his face projected like a monkey, with thick lips protruding an inch beyond his nose. He had a comparatively long body, with short, bony legs. He had a grayish, bristly mustache, but no beard. The woman was well developed and about the same size. She had a yellow tint, with long, straight, black hair and a pleasant expression. They were dressed in loose cloths, and though they ate flesh, they lived principally upon honey and nuts.

The chief geographical events of the year in Africa were the exploration of the Victoria Nyanza by Stanley, and the journey across that continent by Lieut. Cameron, from Lake Tanganyika to Benquella, on the western coast, about latitude 11° 56' south. An Egyptian geographical society has been organized by the liberality of the Khedive for the purpose of exploring Northern Africa. It has already 300 members, and an annual income of \$7,000.

The New Metal, Gallium, and its Salts.

M. Lecoq, in a communication to the French Academy, states that he has succeeded in obtaining the metal gallium and its salts in a tolerably pure condition.

When deposited by electric action, gallium forms a very adherent layer; it is hard; it is polished with difficulty by friction with an agate braisher. The metal thus acquires great brightness, and appears whiter than platinum. When the electric current and the relative dimensions of the electrodes are properly regulated, the gallium presents a beautiful dull surface of silvery white, finely granulated, and interspersed with small brilliant points, which the microscope shows to be crystals.

Gallium, deposited on a platinum plate, is not much oxidized during washing in cold or boiling water, nor on being dried in free air raised to about 200°. It decomposes water acidulated with hydrochloric acid in the cold state, and more rapidly in hot state, with a brisk liberation of hydrogen.

Notwithstanding the undoubted rarity of this new metal, close researches seem to indicate that it exists in small quantities in nearly all blends. The extreme sensibility of its spectral action is liable to lead to an over-estimate of its quantity.

M. Lecoq, after enumerating the actions and proportions of the various salts of gallium, adds: "If there is no error as to the nature of the metal, the existence of this salt fixes the atomicity of the new element, and attributes to its oxide the same chemical functions as that of alumina. The oxide of gallium, then, will be written Ga₂O₃.

PENETRATION OF ROOTS IN ROCK.—In the Paris exposition of 1867, some specimens of white marble were exhibited in which were furrows channelled in the stone by the action of the carbonic acid exhaled by the growing roots of adjacent trees. M. S. Meunier reports a similar case at Orsay, in a still more resisting material, close-grained siliceous sandstone. Here the roots of some elm trees were found to have made their way into the rock by decomposing the very small portions of calcareous matter cementing together the siliceous particles. An entrance thus effected, they seem to have acted, in part chemically by dissolving the cement, in part mechanically by forcing the grains of sandstone apart. In this respect the fibrils to have been much more active than the larger roots. Eventually, they died off for lack of nourishment, and the greater part of their remains disappeared, leaving only tubular molds, varying in length from three-one-hundredths to three-tenths of an inch, with sides bearing the exact imprint of the roots. These were rendered more conspicuous by the yellowish stains due to the subsequent infiltration of surface water impregnated with iron. The case affords a good example of the manner in which roots occasionally penetrate into masonry, and is not without significance in a geological point of view, as showing that traces of recent vegetation may occur in rocks of older date. —*Comptes Rendus*.

SCIENTIFIC RESEARCHES IN THE CASPIAN SEA.—Oscar Grimm, the naturalist, has found a rich zoological field in the Caspian sea. He has examined the locality during but three months, dredging most in the bay of Balkan, at a depth not exceeding 150 fathoms, and has found 80 new species. Six of these are fish belonging to *Gobi* and *Bentho*, 20 are mollusca (mostly *Cardium* and *Dreissena*), 35 are crustaceans, including gigantic forms of *Gammarus* (water-fleas) and *Myis*, and 19 are annelids. He found but little life on the eastern side, owing to the outfall of sand from adjoining steppes; but on the west side life was very abundant, a single haul of the dredge bringing up over 600 individuals of several different families. The forms of animal life in the Caspian show a much closer affinity with those of the sea of Aral and Arctic ocean than with the Black sea.

AN INTERESTING EXPERIMENT.—A very pretty lecture experiment arranged to show the low temperature at which a flame may exist, may be pronounced in the following manner: Boil in a long necked flask, in which a tube has been

fitted with a tight cork, a small bit of phosphorus with five times its weight of lime. As the phosphorated hydrogen issues from the tube, it burns with a pale green flame, at so low a temperature that a common friction match may be held therein for a considerable time without taking fire. The experiment is somewhat dangerous, and should be made with great care, and with only a very small amount of phosphorus.

MECHANICAL PROGRESS.

A NEW SOURCE OF POWER.—M. G. Hanrian, of Meaux, France, has proposed a new source of power, obtainable in localities wherever an absorbent strata can be found underlying an upper strata, which holds the water near the surface. In such localities Mr. Hanrian sinks a well of large diameter down to the water bearing strata, and from the bottom of that sinks another smaller well down and into the absorbent strata. The lower well is curbed up from four to six feet or more, so that when the water in the upper well rises above the curb, it overflows into the lower well and from thence passes off into the absorbent strata. By this device there will always be a depth of water in the upper well equal to the height of the curbing of the lower one. The wells being thus arranged, a chain pump is placed in the lower well with the upper end of the chain passing over a pulley just above the top of the main or larger well, and so arranged that all the water that passes down must act upon the buckets connected with the chain. With this arrangement it is seen that when the water from the upper overflows into the lower well, the weight of the water will drive the pulley placed above the large well. Now, if another chain pump is properly placed in the upper well, and passed over a pulley on the same shaft on which the pulley already described is placed, it is evident that the column of water descending from the upper through the lower well into the absorbent strata can be made to raise another column of water of equal weight from the upper well to the surface. Thus a well so situated and arranged can be made to pump itself—and we have a new source of power which may be utilized as above indicated.

INVENTION RELATING TO CAR WHEELS.—A recent invention relating to the casting of chilled car wheels consists in constructing the metallic annular chill with annular air chambers at the points of the interior surface of the chill where the outer periphery of the flange of the wheel is formed, and also at the point where the outer horizontal surface of the tread is formed, by means of which the central portion of the tread, which receives the greatest wear, is allowed to harden; but the outer periphery of the flange and the outer surface of the tread are prevented from rapid cooling by the new conducting air chamber, and the metal at these points is molded and preserved in its full strength and tenacity, which is said to be a result to be greatly desired in view of the fact that, while the process of chilling hardens the iron, it greatly impairs its tenacity and strength.

AMERICAN STEEL.—An Englishman, now an ironmaster in Pennsylvania, says that steel is now being made about as cheap as iron; that every mill that is adapted to making steel has more orders than it can fill, and that such mills are running night and day on rails. Mr. S. B. Lowe says:—"In the Northern States the steel ores are almost exclusively confined to Lake Superior and Iron Mountain, both of which are many hundred miles from fuel. In Chattanooga, East Tennessee, we have a number of ore beds that are already being turned into metal and sold in advance to the manufacturers of steel. Still we must say that we as yet know but little of what we have. We have hundreds of ore banks that never had a pick nor shovel in them, let alone the fact that they have never been tested."

DYNAMITE OPERATIONS AT BLAST FURNACES.—For some time past one of Messrs. J. Brown & Co.'s blast furnaces at Sheffield has been losing iron, and it had at last to be stopped and blown out. The iron was then found to have got through the concrete bottom of the furnace, and that there was a mass of nearly 200 tons of iron in its place. Efforts were made to break this solid mass up by means of powder, but ineffectually, so that resort has now been had to dynamite. This powerful explosive has already dislodged about half the block, pieces of eight to 10 tons being blown off at each shot. —*Engineering*.

BEAM END PROTECTOR.—This is a new device, just patented by Mr. Norman McLellan, of Chicago. It consists of a tin hood, made to fit tightly over the ends of beams and joists, serving the two-fold purpose of preserving them from damp and protecting them from fire. It is well known that beams and joists, in party walls, often approach so near together that fire is readily communicated from one to the other, and it is safe to say that millions of dollars have been lost in consequence. The device is simple, but none the less valuable on that account, and it is to be recommended to builders.

The Danforth locomotive and machine company, at Paterson, N. J., is about to build 10 heavy locomotives for the Central Pacific railroad.

GAS FIXTURES.—This manufacture, though of quite a modern date, has nevertheless become one of the most important industries of the day, whether we regard it in the sense of the utilities it serves, or in the love of beauty to which it administers. A few years ago most of the gas fixtures used throughout the world were manufactured in England and France. Now, all such manufactures for this country are made at home, and large quantities sent to South America, Mexico, etc. The extent of this branch of manufacture in the United States may be inferred when we reflect that nearly all the dwellings, stores and shops in cities and large towns are supplied with gas fixtures, to say nothing of the numerous large residences and manufactories in isolated localities, the proprietors of which manufacture their own gas from some one of the numerous methods which have been invented with such an end in view. Progress in the knowledge of gas manufacture has been quite rapid, and is of late leading strongly in the direction of procuring gas from coal oil, which promises to work a great reduction in price and a more general use of gas instead of oil. The cheapening of gas and the simplifying of its manufacture will lead to a still greater demand for gas fixtures.

LOCOMOTIVES WITHOUT STEAM DOMES.—A correspondent of the *Scientific American* says: "The Boston and Albany railway company has some 240 locomotives, most of which have no steam domes; and if you ask the men who handle these engines how they carry their water, they will tell you that no engines work drier steam or less water than they do, under all circumstances. It is well known that much of the track of this line, on the mountain slope between Westfield and Washington, lays on a grade of 83 feet per mile. Steam domes are not only expensive, but are a decided injury to a boiler, and if locomotives work as well, they are certainly much better without them. This company is continually building locomotives without domes, which seems to be the best evidence possible that they are as useless as a steeple to a church." The journal from which we quote remarks upon the above: "There are many locomotives which have no steam domes. The celebrated Crampton engines, made in 1847, had none, and gave excellent results. It is usually considered, however, that drier steam is obtained from the top of the dome than from the shell of the boiler."

PARSON'S MANGANESE BRONZE.—A new variety of bronze, containing manganese, is just being introduced by Parson's white brass company. It is stated to be very valuable for all kinds of small work wherein gun metal is now used, and it is capable of being forged like iron. Specimens have been tested at the Royal Arsenal, Woolwich, with the most satisfactory results—yielding at from 14 to 16 tons pressure per square inch, and breaking at from 22 to 30 tons. Its ratio of elastic to ultimate was from 39 to 71 per cent., and its elongation from 8 to 35 per cent. In these trials six different specimens were employed—three of which were cast in iron molds and three forged from the same castings. The latter were of course much superior. The difference in the mode of preparing the test pieces for trial accounts for the wide range of results, especially in the matter of elongation. The sectional area of the test pieces was .533 square inches, and their length two inches.

A NOVEL PIECE OF DRILL WORK.—The American Diamond rock boring company, of Providence, R. I., lately finished the job of taking a 24-inch core out of the columns of the State capitol at Columbus, Ohio, the immense pillars in their solid state being considered too heavy for the foundations. This company are now shipping \$50,000 worth of their drills to the German government, and also filling orders from Sweden and Chile.

A VERY good impression of any article of metal having a flat ornamented surface may be taken by wetting some note paper with the tongue and smoking it over a gas flame. The article is then pressed upon the smoked paper, when, if the operation be carefully conducted, a clear impression will appear. This can be made permanent by drawing the paper through milk and afterwards drying it.

NEW TELEGRAPH INVENTION.—A new key is being put into the telegraph offices on the Pennsylvania railroad. This is a new invention, by which a dozen or more wires can be sounded with one key. Mr. Hussey, the inventor, is building a factory for the manufacture of the instruments.

NAPHTHA AS FUEL.—Experiments made with naphtha as fuel for steam engines in the south of Russia are stated to have yielded such satisfactory results as to induce the Russian government to order its use in future in all vessels stationed on the Caspian.

A PASSENGER locomotive is being built in the machine-shop of the Philadelphia & Reading railroad company, at Reading, Pa., for exhibition at the Centennial. It is to be entirely the work of apprentices.

COMPARATIVE COST OF STEAM POWER.—According to Ackermann's *Gewerbezeitung*, human labor costs, on an average, 90 times, electricity 70 times, and horse power 10 times as much as steam power.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

A HANDSOME FIND.—Amador Ledger, March 18: On Monday last Joseph Cuneo was engaged in wheeling a barrow full of retuse rock through Volcano, when he detected gold in a large piece of quartz which had been washed by rain. He immediately secured the prize, and found it to be auriferous throughout, large chunks of gold being visible all over it. The specimen is said to contain from \$50 to \$1,000 worth of gold—one of the highest finds that has been made in these parts for years.

DOING WELL.—We mentioned a few weeks ago that Richard Stocken had discovered a rich quartz vein a few miles above Volcano, and that he had washed the dirt in the vicinity of the lead, realizing a handsome sum therefrom. He is quietly pushing his operations, saying little to anybody, and giving no clue as to how he is panning out. He cleans up occasionally, and the impression is general that he has struck a splendid thing. The whole neighborhood thereabouts will undoubtedly be swarmed with prospectors the coming spring and summer.

THE MOHAWK MINE.—This mine is located some four miles beyond Volcano. Work is being pushed ahead as rapidly as the weather and facilities will permit. The vein is narrow, from 12 to 18 inches in width, but exceedingly rich in gold. There is a large quantity of rock on the dump awaiting shipment, but the roads are too heavy at present to admit of hauling it to the mill.

HYDRAULIC CLAIM.—The hydraulic claim of Messrs. Stickland & Hughes, seven miles east of Sutter Creek, is kept constantly at work, and the prospects are very encouraging. The first clean-up, made some weeks ago after a short run with very little water, realized only \$94. Now they have got the claim into thorough hydraulic order, and the outlook is flattering. A nugget worth \$20 was lately picked up in the sluices. The owners are energetic, enterprising men, and deserve success.

MAXIMILIAN MINE.—The Maximilian company have leased the old Rose mill on Sutter Creek for one year, and intend to put it in working order at once. The mill has been in long time, and has fallen into a dilapidated condition. The mortar block is badly out of wood, work rotted away, and flume and ditch in bad order. It will cost from \$2,000 to \$3,000 to put it in repair. The mill is only about half a mile from the mine.

BONANZA MINE.—We are informed that a rich body of ore has been struck in the south drift of the Bonanza mine at Drytown. The ledge is also widening out finely. Men are now engaged in retimbering the shaft. As soon as this is completed, sinking operations will be resumed.

CALAVERAS.

GRAVEL MINING.—Calaveras Chronicle, March 18: Gravel mining is progressing briskly again, now that the temporary lack of water, caused by land slides on the ditch, is no longer felt. All the hydraulics are in full blast and the tunnel claims running full handed. Lively times this spring.

GOING TO CLEAN UP.—A clean-up is to be made in the south hydraulic claim this week—the first of the season. The sliding of the hill has kept the fire pipes and machinery buried under the winter, to prevent being buried alive, that they haven't had time to lift a rifle since the rains set in. Now Mr. Veith intends unloading his sluice boxes.

SAN BRUNO.—It is expected that the "raise" in the San Bruno will be completed this week. The new hoist-lifts will be put up immediately, and the new machinery having been purchased and only awaiting better roads to be transported to the mine. With the opening of spring the upper country will be resonant with quartz mining music.

ALL RIGHT AGAIN.—The land slides that have lately impeded the flow of water in the ditch and somewhat interfered with mill operations, have been removed, and everything on the line of the canal is lively again. There is an abundance of the aqueous and good use is being made of it all.

INYO.

RUNNING.—Inyo Independent, March 10: The Union Consolidated company, at Cerro Gordo, are now running out bullion, though as yet they have been able to start but one furnace—the Baudry—on account of the snow rendering it impossible to obtain coal in sufficient quantity. It will be but a short time, however, before both furnaces will be in full blast.

DARWIN.—Cor. Bakersfield Courier, March 16: Most of the furnaces are idle at present, owing to lack of coal. The wooded district upon which Darwin is dependent for coal lies in the Coso range, eight or ten miles west of Darwin, and the snow is so deep that the coal production has been suspended for a time. The suspension will not be of long duration, and as soon as the snow melts the work will be resumed, and the Darwin furnaces will be running on regular runs of coal. Mr. Blanche has recently returned from a prospecting trip to the Lee district, some 15 miles northeast of Darwin. The character of the ore is totally different from that at Darwin, and is found in a range of low broken hills distinct from the Darwin range. Free milling silver ore is found here, but mostly in narrow ledges, and some of the assays are very high. As a general thing the ore lies in bunches, but the Cosos and Valentines show well defined leads. The ore is considered to be equal to the best White Pine. A five-stamp mill will be running by the first of May, and then there will come good reports from the Lee district.

MARIPOSA.

MARIPOSA LAND AND MINING COMPANY.—Mariposa Gazette, March 18: For quite a long time we have been without advice of the progress of the River tunnel and surrounding works, but it seems while we have been waiting they have progressed steadily. This main heading is now in 3,322 feet, with the face in very hard trap rock—no water to speak of. The boring by the Diamond drill from the heading of the west branch drift of this tunnel has proved successful. At a distance of 331 feet a body of quartz was struck through which the drill bored for 14 feet. The rock core taken out showed conclusively that it came from a vein, especially as a "rough" was met just previous to striking quartz. All credit is due to the engineer in charge of the Diamond drill, Mr. Frank Thoma, for the work taken in running his machine, the more as the space in which he operated was very limited. We are thoroughly satisfied that the Diamond drill, judiciously used, will be the means of revealing the hidden wealth of this estate. The body of ore just discovered is at a depth of 70 feet below the 1,400-ft station, so that the River tunnel must be driven 100 feet, and a cross-cut eastward of 70 feet before reaching the vein. Prospecting will be still carried on to further examine this deposit.

WASHINGTON MINE AND MILL.—This rich mine, which is located about two miles northwest from the town of Hornitos, in this county, and about which but little has been said, has been incidentally heard from. We learn, through a friend who resides in the vicinity of the Washington mine, that notwithstanding the severity of the weather, which has been so prevalent of late, has not occasioned any damages or delay in or about the premises, and that the 20-stamp quartz crushing mill and chlorination works are moving gently along, as though the elements of nature were undisturbed, as

compared with a mid-summer. This mine gives employment to about 75 men, who work underground, besides about a dozen upon the top, and about the mill. There are about 200 tons of ore already upon the dump which, as a matter of precaution, in case of a delay in the hoisting works of mine, is kept on hand, so that the mill can proceed until any cause of delay in the mine can be removed. The ore is rich in sulphurets, which are estimated at \$75 per ton, and the gold is saved therefrom by the process of chlorination, which adds largely to the average yield of the mine. The shaft is about 300 feet deep. There is no water below the 300-ft level, and the key consequence. The mill, mine, pumps and chlorination works are all of the first order, and in most excellent condition. The clean-up occurs every two weeks, and it is manifestly certain that this mine and its surroundings, which is under the direction of Mr. George E. Webber, superintendent, and Moses Rogers, an underground mining boss, afford to its owners a liberal dividend.

NEVADA.

OMAHA MINE.—Foothill Tidings, March 18: As we intimated the probability of, last week, the Omaha mine of this place declared its first dividend a few days since. The mine has been in the pockets of the stockholders of \$1 per share. The Omaha mine is owned by a board of directors, also, at the request and consent of holders of more than two-thirds of the capital stock of the company, decided to change the principal place of business from Sacramento to San Francisco, and change to be made on the 15th of April next. The annual meeting of the stockholders will take place at the Omaha office, 1015 Broadway, San Francisco, on the 15th day of April next.

SILVER.—Nevada Transcript, March 18: Most of the mines of this county yield only gold by mill process, but experiments by the Fryer process prove that many of them contain as much or more silver than gold. We saw some specimens of rock recently taken from the Independence mine, after it had gone through the roasting process of Fryer's works, in which chunks of silver of different sizes were thickly scattered all over the surface. The Star ledge, owned by Perrin & Brown, at Forest Springs, is another instance. It really contains more silver than gold, yet none of the silver has ever been saved by mill process. If Mr. Fryer had gone no further than this step, his invention, in our opinion, would have been as much value to the mining interest of the world as all the improvements heretofore made in quartz mining.

PLACER.

MINING ITEMS.—Dutch Flat Forum, Mar. 16: The storm mentioned in our last week's unabated fury till Monday afternoon, when it cleared and was pleasant during Tuesday and yesterday. The miners who have been waiting with anxiety for a few days of pleasant weather to complete outside work, eagerly took advantage of the circumstance and commenced work with unusual vigor. The men working on the splendid string of pipe being laid to lead the water into the Buckeye claim, and the men making the alteration in the Franklin pipe, changing it from the ditch of the South Yuba canal company to the Cedar Creek company, commenced work promptly and are pressing forward with all possible haste. The tunnel leading into the Dutch Flat claim is being driven with unusual speed, the contractors having made 207 feet last month. The work of constructing the sluices in the Yankee tunnel which was suspended owing to the impossibility of getting lumber has been resumed. The Yankee claim cleared up on Friday, the result being unusually good for the number of days run. The Pacific and Central claims have also cleaned up and are now re-ditching. The ditches are having a very rough time. The water has again been out of the ditch of the Yankee claim since our last, and the ditch of the Cedar Creek company covered with snow slides about a mile above Owl Camp, which shuts off the water so that that company now uses only about 800 inches running. The foreman of the latter ditch, John Foster, writes that he has been on that ditch for 10 years, but never has seen so much snow as at present. If the water does not hold out late in the summer we shall conclude that all signs fail.

SISKIYOU.

A MINING ENTERPRISE.—Yreka Union, March 18: Mr. Frank Abrams, who resides at the head of Coffee creek and Simon river, in what used to be Klamath county, has been prospecting in the vicinity of the latter river, and has discovered considerable ground in his vicinity for mining operations, and as soon as they can get in will commence work. One of the locators was up in the vicinity prospecting around sometime during last summer, and this company is formed on the result of his observations. The miners of Scott valley are jubilant. They have made a successful run, and are now commencing taking, which will no doubt insure them a golden harvest. Messrs. Kingery & Cory have found fine prospects in their quartz ledge, and are now well satisfied that it will pay for the construction of a mill. Messrs. Hopper & Son also intend to build a mill this coming summer on Rattlesnake creek, for crushing rock in that vicinity. We may therefore look for lively times in the mines.

SONOMA.

QUICKSILVER.—Russian River Flag, March 18: The Phoenix mine is working 12 men, prospecting, and finding some very fine ore on the lower level. Only a few more runs now, the furnace being temporarily closed down. In the last six months 511 dasks were produced, a good yield.

The Taylor mine, situated about 16 miles northeast of the upper end of Clear Lake, yielded one-half pound of pure quicksilver the other day from one common tank of ore, and that, too, not having been selected.

Nevada.

WASHOE DISTRICT.

BELCHER.—Gold Hill News, Mar. 16: Daily yield, 465 tons of ore, keeping the mills all running up to their full capacity. The ore breasts are all looking finely, and are yielding the usual amount of good ore. The prospecting department is working directly from the 1500-ft level is showing a steady improvement. The entire mine, in fact, is looking better with every step of development now making. The air shaft is being sunk at a rapid rate below the 1500-ft level. It is expected that the ground will be amply dry enough to start the pumps to working directly from the 1600-ft level, when once they are in running order.

JULIA.—Sinking the shaft is making excellent headway, the bottom still in quartz and ledge material of a highly favorable character. The face of the main southwest drift on the 1600-ft level has passed through the clay and porphyry encountered last week, and is now almost the grade of the low-grade ore. The prospecting department has just passed through to be nothing more than a large horse, and that the vein on that level is actually 400 to 600 feet in width.

CHOLLAS-POTOSI.—No ore is being extracted at present, owing to the bad condition of the roads. Sinking the combination shaft is making steady progress, the bottom during the first part of the week having run in very soft ground, with a strong increase in the flow of water.

NACARA.—The erection of the hoisting works is about completed, ready to resume the sinking of the main incline. At the time of the suspension of the work in the bottom of the incline last fall, some very favorable ore indications were encountered.

AMERICAN.—The erection of the new hoisting and pumping machinery is almost finished, ready for operation. It will not be long before the water is drained.

BULLION.—The main northeast drift on the 2000-ft level is steadily advancing, without a change in the porphyry formation. The north drift on the 1400-ft level has been cleared and repaired a distance of 216

feet. It is the intention in a very short time to start a winze downward from the drift to connect with the raise from the level below. This will give a good ventilation of the lower levels. It is the intention also soon as the north end of the drift on the 1400-ft level is reached and the repairs completed, to drive the drift directly ahead toward the north line. The company have yet 450 feet of virgin unprospected ground on the north end of their claim, of the character of which on the 1400-ft level nothing whatever is known. The ledge on the 800 and 1000-ft levels in that portion of the mine was over 150 feet in width, carrying rich streaks of gold ore, and it may be that a development in that portion may yet prove it to be the best portion of the mine.

CONSOLIDATED VIRGINIA.—Daily yield, 750 tons of ore, keeping all the mills steadily running. The ore breasts were never showing more favorably than at this time, and the future prospects of the mine never more flattering. The yield of bullion up to the present time is over \$300,000 ahead of what it was at the same date last month, and if no accident or unavoidable delay occur before the end of the month, the yield will be out short of \$3,000,000. The east drift, running in the east country rock, to connect with the O. & C. shaft on the 1300-ft level, is going steadily ahead, the face still being perfectly dry, showing almost beyond a doubt that there is an intervening body of clay between this drift and the strong body of water now being drained in the shaft.

MEXICAN.—The week has been mostly spent in driving the main drift on the 1405-ft level further to the northward, and in cross-cutting to clear the width and extent of the ore body recently struck in that portion of the mine. The prospecting shows that the ore body is undoubtedly large, and has also proven that the quality of the ore is such as to pay well for mining and milling. The full limits of the discovery cannot as yet be known, but enough has already been developed to prove that it is of great value, and the chances are that it will prove itself to be the richest and largest body of paying ore ever yet developed on the north end of the Comstock. The ore, while averaging well, has rich and poor spots, some portions assaying into the thousands, while others run quite low. The finding of a continuation of paying ore to the northward is not only a good thing for the stockholders of the Mexican, but is also a great encouragement to all neighboring prospecting claims, bringing as it does, these developments right to their very limits.

OPHIA.—Daily yield, 150 tons of ore, keeping the Empire State and Nevada mills steadily running. The Windmill mill has not yet started up, but had condition of the roads preventing the delivering of a regular supply of ore. The ore breasts are yielding well, and show no signs whatever of depletion. The new and powerful incline hoisting machinery was started up day before yesterday, everything working with the utmost perfection and smoothness.

CALIFORNIA.—The north drift on the 1550-ft level has about 20 feet yet to run to connect with the bottom of the winze now sinking below the 1550-ft level in cross-cut No. 6. Both the face of the drift and the bottom of the winze are still in rich ore. The pumps are hoisting a steady stream of about 25 inches of water, miners' measurement. They are capable of lifting 40 inches with the same case, so that there is no immediate danger of a flow that they cannot master.

COSMOPOLITAN.—The face of the main drift north, following the vein, continues in the same excellent ore which has characterized the last 30 or 40 feet, showing considerable improvement, however, as further advance has been made in the sinking of the vein. The face of the drift is now in ore which gives high assays, and heavy additions to the already well loaded dump. This main drift tunnel is now in nearly 800 feet, and cross-cutting in the good ore vein at the north end will soon be commenced.

SIERRA NEVADA.—The east and west prospecting drifts at the 1500-ft station are steadily advancing in very favorable ore, and are capable of sinking 40 inches at the 700-ft level of the north drift from the old shaft is going steadily ahead, the bottom in good working ground.

SILVER CITY.—The ore is being stoped out north and south from both upraises. The breasts are looking and yielding well at all points, giving the usual daily addition of ore to the abundant accumulation already on hand.

LADY WASHINGTON.—Very good progress continues to be made in sinking the shaft, the material met with being of the most favorable character.

SUITO TUNNEL.—Total length of the tunnel last evening, 12,613 feet. The material met with works very favorably, allowing of more rapid advancement than heretofore.

OVERMAN.—Sinking the shaft is making much better progress than for some time past, although the rock in the bottom is yet very tough and hard to blast.

KOSUTH.—The main shaft drift on the 350-ft level is steadily advancing, the face in ore which assays rich in gold. The ledge on the 350-ft level is steadily widening and showing more favorable to the southward as the drift advances.

FLORIDA.—The grading for the new and powerful hoisting machinery is fully completed and the machinery is being put in position as fast as it arrives.

SULLIVAN.—Considerable improvement is met with in the face of the east cross-cut, better quartz having been found during the week than has yet been shown at this level. It is in fine looking streaks which assay from \$30 to \$50.

DAYTON.—Both the north and south drifts on the 500-ft level are advancing in a very favorable formation, running parallel with the ledge.

NORTH OMBON.—Drifting north from the newly opened 250-ft level is actively commenced and making excellent progress. The width of the vein at this point is greater than the last above, and south of the ore assays very high, with plenty of it in sight.

GOULD & CURRY.—The excavations for the foundations for the new pumping machinery will be commenced in a very short time.

SAVADE.—The water in the shaft remains stationary at the 1300-ft level. Preparations for the erection of the new and powerful pumping machinery are going steadily forward.

WENDELL.—Mr. J. P. Hutchinson, the very efficient superintendent, is now in San Francisco contracting for steam hoisting machinery for driving the work at a much more rapid rate.

NORTH DAYTON.—The ore vein gives assays of from \$30 to \$50 to the ton, and is increasing in width.

ALTA.—The shaft has again been drained and the sinking resumed.

OWEN POINT.—Daily yield of ore, 360 tons, keeping the mills steadily running.

ROCK ISLAND.—The prospecting drifts at the 850-ft level are steadily advancing in very favorable vein formation.

EMERY.—More streaks of quartz continue coming in at the bottom of the shaft, and the prospect is that these streaks, all of which give good assays, will consolidate into a ledge of pay ore.

BEST AND BELCHER.—Repairing the main drift connecting with the Gould & Curry on the 1700-ft level is going steadily ahead, the damage to the drift proving much greater than was at first expected.

LEVATHAN.—The shaft continues in the same excellent ledge material mentioned last week, with continued improvement.

LADY BRYAN.—The south drift from the 500-ft station is steadily advancing, the face in a fine quality of quartz, grading into gold ore. The prospecting drifts on the 350-ft level are all showing well, and the west cross-cut, No. 1, is steadily developing a fine body of pay ore.

KNICKERBOCKER.—The greatest activity is exhibited both in sinking the shaft and opening the drifts on the lower levels, preparatory to cross-cutting the ore vein. Six and eight-hour shifts are employed at all points in the mine.

UNION CONSOLIDATED.—The winze now being sunk below the 1300-ft level is steadily advancing downward, cutting in its course many fine streaks of good ore. The situation of this winze is some distance west of the new ore body discovered by the north drift in the Mexican ground, so that it cannot be expected to strike the same ore body until it has reached the 1465-ft level and a drift has been run from the bottom far enough east to reach the same portion of the vein.

YELLOW JACKET.—All of the drifts are in porphyry. The cross-cuts on the 1740-ft level continue to look quite favorable.

TRJAN.—The erection of the new hoisting works building and the new steam hoisting machinery is making steady progress. About 40 men are employed on the work.

LEO.—The extraction of ore for milling was commenced yesterday. It is estimated that there is an abundance of ore in sight; enough to keep a 10-stamp mill running for eight months or more.

BALTIMORE AND AMERICAN FLAT.—The east drift on the 1050-ft level is steadily advancing, the face in very favorable ledge formation. The 1150-ft station is completed and ready to start a prospecting drift at that point.

HALE & NORCROSS.—Nothing doing in the mine on account of the flooding of the lower levels by the water from the Seave.

IMPERIAL-EMPIRE.—The north drift, on the 2000-ft level, has passed through the broken up formation of quartz and porphyry, reported last week, into a fine formation that promises the opening of a large body of pay ore.

Arizona.

ISABELLA MILL AND MINE ON BIO BUO.—Arizona Miner, March 12: Mr. C. E. Hitchcock commenced work on the Isabella mine with a small force, under Billy Gavin, on the 1st of November. They now have four shafts from 10 to 60 feet deep, and levels run 50 feet each way, showing a vein of ore from two and a half to four feet wide. They have cut out 600 tons, and are averaging two and a half tons per day to the mill. Work commenced on the mill and build up December 1st, and in 15 days the ditch, water wheel, road, etc., were completed, and in 90 days the 10-stamp mill was running with 300 tons of ore in front of the batteries. This is perhaps the quickest work in the way of mill building and mine development on record. Mr. J. J. Hill, who has had charge of the erection of the mill and water wheel, was in town on Tuesday, and reports the mill running, with snow enough in the mountains above it to insure water to keep it going for the next three months. Mr. Hill says the Isabella has developed a good mine in every shaft, and looks as fine as any vein he has ever seen. The vein is narrow on the surface, but at a depth of 25 feet and thence downward it fills the entire size of a working shaft. Nothing but milling ore is hoisted out; there is no waste. Prospect shafts along the lead for 3,000 feet show the same character of ore as that already mined.

Idaho.

THE ALTURA BONANZA.—Idaho Avalanche, March 10: In a private letter received yesterday from Rocky Bar the following reference is made to the quality and quantity of the rich rock recently extracted from the big ledge at Atlanta: "At Atlanta the Monarch company have out and sacked for shipment \$300,000 worth of ore which has been taken out this winter at a cost not to exceed \$7,000, and allowing an extreme outside limit \$10,000 for further costs of handling, shipping, reduction and commission will leave the small little sum of \$283,000. The prospects of that camp are very flattering, although for some time to come the great force of men can find employment." From other sources we also learn that Alturas is looking up splendidly, and with the expected new capital that will probably be brought in this spring, for the purpose of working up the mines on a larger scale, the most favorable results are anticipated. There is not a more promising camp on the Pacific coast.

Montana.

PLACER MINING.—Montanian, March 12: The prospects at this writing are very favorable for an early commencement of operations in the placer mines of this country. On account of the mildness of the winter the frost has not penetrated so far into the ground as of yore, and the ground is now in a very favorable condition for prospecting. The indications are that the yield from our placers during the season of 1876 will be fully up to the average of the past few years, if not actually greater, and we confidently look forward to a prospecting season for this important interest. Some work has been done during the winter months, and the sluicing of the gravel which has been uncovered will produce quite a large amount of money in a few weeks. "Ye honest miner" is hopeful and we trust to see his wishes fully realized.

Utah.

STAR DISTRICT.—Cor. Salt Lake Tribune, Mar. 19: The Big Bonanza is looking better than ever. The parties who bought it immediately put on a gang of miners and have sunk the prospect shaft to a depth of 54 feet in solid ore of a higher grade than when first struck. Work is being pushed rapidly to the surface as fast as circumstances will permit. It will undoubtedly be a second Comstock. The Wah Wah smelter, owned by Cullen & Ryan, is being removed from its original location, and is to be erected in close proximity to this huge mine. Other mines in this district are looking well. Everything hides fair for lively times in Star and San Francisco districts this spring. The smelter at Shantite is running and turning out bullion by the car load. South Camp is looking nicely and work still continues on the Rebel and other mines at North Camp. The Dike mine is improving.

SALE OF THE NEW IDRIA MINE.—The officers of the New Idria quicksilver mine took occasion last week to deny that they had sold the property, coupling the denial with the statement that they had not disposed of it to McGarraghan, the claimant in the long-pending lawsuit. It now appears that arrangements have been made for the sale of the mine on the 1st of September next—not to McGarraghan, who still presses his suit and waives nothing of his claim, but to Montgomery Blair, of St. Louis, and the price agreed upon is \$1,000,000. The deed drawn up makes an absolute disposal of the mine by the present owners, who have maintained possession throughout the protracted litigation, to Blair, upon condition that \$400,000 be paid on the 1st of September and the remaining \$600,000 be paid in five years, a mortgage at seven per cent. being taken as security.

Fortify and tone the feeble cough-torn lungs with HALE'S HONEY OF HOREHOUND AND TAR, and they will soon assume their healthy and regular action. It is an absolute safeguard against consumption. Pike's Toothache Drope cure in one minute.

WOODWARD'S GARBERS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

The Uses of Aluminum.

When we consider the excellent qualities possessed by this metal, its color, brightness, unchangeableness in air, and in sulphuretted hydrogen, that it is not injurious to the health and can be worked in any shape, it seems remarkable that it has found so little use, and that the great hopes which greeted its preparation according to Deville's process are so far from being fulfilled. The price of aluminum would be considerably less if it were made in large quantities, as it depends on the price of sodium, the manufacture of which could also be conducted more cheaply if there were a certain and large demand for it. The advantages of vessels made of aluminum are not so evident and conspicuous as to be able to easily overcome old habits.

At the London exhibition of 1862, numerous articles of aluminum were exhibited; the Paris exhibition of 1868, and the Vienna exhibition of 1873 showed that the interest in this "silver from clay" had died out.

Aluminum made by Deville's process was used at first as ornaments and other articles of luxury. On account of its brightness the tubes of opera and spy glasses were made of it. In physical apparatus and all fine instruments where weight is an objection aluminum replaces other metals with advantage. Saber sheaths and dagger handles have been made of it. The eagles on the flagstaffs of the French army are about four and a half pounds lighter since they have been made of aluminum. As the metal can be drawn out to the finest wire, it has been used for embroidery, lace, fringe and other decorations. They have some advantages over the same articles when made of silver, being lighter and they do not tarnish.

Nevertheless the use of aluminum has, as we have said, greatly diminished. Aluminum jewelry is scarcely seen at the present day. Opticians still use it for spy glasses and the like. Recently it has been much employed for surgical instruments. In the atelier of C. Schmidt, in Berlin, a considerable quantity is consumed in the manufacture of splints.

Although there is no mistaking the fact that the high expectations with which the appearance of aluminum filled the public mind have not been fulfilled, yet the aluminum industry has a safe guarantee of its existence in the use of the metal for aluminum alloys, which are capable of the most extensive use on account of their excellent qualities.

Aluminum will alloy directly with most metals, generally with strong heat, which may increase up to the glowing point. Small quantities of other metals affect the properties of aluminum, while, contrawise, small quantities of aluminum change the properties of other metals.

The alloy of aluminum with copper, aluminum bronze, is of the greatest importance in the arts. According to Tissien, as little as one per cent. of aluminum, added to pure copper, considerably increases its ductility, making it more fusible, and gives it the property of completely filling the mold, making a dense casting, free from air bubbles. At the same time the copper becomes more capable of resisting chemical reagents, increases in hardness without losing malleability, and unites in itself the most valuable qualities of bronze and brass. The color of the alloy is almost a copper red.

A copper alloy with two per cent. of aluminum is used in the studio of Christofle, in Paris, for works of art. It works well under the chisel and graver.

The true aluminum bronzes, namely alloys of 90 to 95 per cent. copper with 10 to five per cent. aluminum were first made (says R. Wagner) by John Percy, in 1855. They became generally known through the researches of Deville.

For the preparation of this alloy, perfectly pure copper must be employed. If to a quantity of melted copper there be added one-ninth its weight of aluminum, the two metals unite energetically, with the evolution of so much heat that the crucible, if it be not exceedingly refractory, softens and sinks together. The bronze obtained is at first very brittle, but by frequent remelting increases in strength and ductility; the right degree is determined by hammering out a piece after each fusion. As a rule, two or three refusions suffice. Probably the amount of aluminum sinks somewhat below the original 10 per cent. Aluminum bronze with five or 10 per cent. aluminum possesses a color very like that of gold. The alloy with 10 per cent. has the color of green gold, an alloy of gold and silver. The alloys polish beautifully, make perfect castings, and possesses great strength; according to Anderson's experiments, an average of 75,618 $\frac{3}{4}$ pounds per square inch. They are also very flexible, and, at temperatures from a dark red heat to near the melting point, perfectly malleable. The castings are perfectly sharp, and can be worked more easily than steel. This bronze engraves nicely, is easily rolled into sheets, and offers greater resistance to the air than other bronze, brass, silver, cast iron, and steel.

These excellent qualities give it a number of uses. In the construction of physical, geodetic and astronomical instruments, it is far preferable to all other metals. In jewelry and articles of art and luxury, it is employed in large quantities. Many kinds of house utensils are made of it, and it is also adapted to journal axle boxes. Gun and pistol barrels, as well as rifled cannon, have been made of it, and have done excellent service. At present the high price of aluminum bronze alone prevents its general use for arms. Morin (who has probably gone out

of the business now) furnished these bronzes at the following rates: 10 per cent. aluminum, \$6.60 per pound; 7 $\frac{1}{2}$ per cent. aluminum, \$5.50 per pound; 5 per cent. aluminum, \$4.40 per pound.

These prices are four or five times as much as tin bronze. In articles where the price of the raw material is of little consequence as compared to the value of the work, as in physical instruments and the like, the aluminum bronze is always to be preferred.—*Iron and Metal Review.*

The University's Needs.

The Special Committee of the Board of Regents, composed of Messrs. H. H. Haight, John B. Felton, W. T. Wallace, J. West Martin, and S. B. McKee, have issued a memorial to the Legislature setting forth the wants of the University. One hundred thousand dollars are needed for the erection of the central portion of a large building for the library and museum, for the Secretary's office, and for additional class-rooms. Ten thousand dollars are required for a wooden building for an auditorium, drill-room and armory of size sufficient to accommodate not less than 1,000 persons. Forty thousand dollars are asked for the erection of a plain, substantial building of brick, 70 feet by 50 and two stories in height, for the Department of Mechanics and Mining. Twenty thousand dollars are wanted for the increase of the water supply to the University buildings and the agricultural grounds. Ten thousand dollars are needed for out-of-door agricultural operations and experiments on the grounds; \$5,000 for the purchase of books for the library; \$10,000 for the improvement of the grounds, and \$60,000 to meet the deficiency between the current expenses of the University and its income. The aggregate sum asked for is \$257,000. In asking for these appropriations the Regents say they are absolutely necessary to maintain the University as the leading educational institution of the State. At the time of the last legislative session the number of students was about one-half of the whole number now in attendance, and before another Legislature convene, should the buildings and other assistance herein be granted, the number will probably reach, and may exceed 600.

THE MINERS' RIGHTS.—The Sacramento Bee discusses the relative rights of miners and cultivators, saying: "It would appear that the miners have the legal as well as the natural right to turn their waste waters with all their burdens into the natural channels or rivers of the country, but that they have not the right to turn them into new or unnatural channels, if by so doing they injure any person or property. When put into rivers they are in their proper place, and those residing on the banks of the stream do so at their peril—or, in other words, take all risks; but when, as in Butte county, the miners throw their tailings out on to the plains through artificial channels, injuring farms, they are evidently trespassing and should be made to pay damages. And the miners themselves recognize this fact, inasmuch as they have in many instances paid for the land so injured. The legislative commission, which is likely to be appointed to investigate the subject and report thereon two years hence, may be of future use; but what is to be done in the meantime? Nothing that we can see, and the past will be repeated."

THERE seems no good reason why the placer mines do not exist south of the Montana diggings on the same belt of country, which corresponds with Wind river section, but we do not believe that anything more than average wages will result from the Constar City affair so far to the eastward of the main Rocky mountain range. At all events, the rush is so far under way, and the military job so fully matured, that the entire country in question is destined to be overrun the present season. It will probably be the last ditch of the American Indian. He is driven into a corner and must go to the wall, and probably the sooner the Black hill game is played out, the better for all concerned. Ere the end of 1876, we look for a reorganization of the map, and "Centennial" Territory created out of Dakota, Montana, Wyoming, etc.—*Lyon County Times.*

TEN MILLIONS IN SILVER.—Probably but few persons have any adequate conception of what \$10,000,000 in silver bullion in one mass would be like. That is the pile that Messrs. Flood & O'Brien propose to exhibit at the Centennial exhibition. This mass of silver would make a solid block 10 feet long, 10 feet thick and eight and one-tenth feet broad, containing 810 cubic feet. One cubic foot of fine silver weighs 727 pounds, and is worth about \$12,000. Ten millions of dollars' worth of silver, therefore, would weigh 588,919 pounds, or nearly 294 $\frac{1}{2}$ tons. Ten tons is usually considered a carload; so it would require a train of nearly 30 loaded freight cars to transport this treasure across the continent.

OVER 250 houses have been erected at Custer City, in the Black hills, and as many more are in course of construction. One sawmill is already running, and two more are en route from Cheyenne. Lumber is selling at \$50 a thousand, flour at \$12.50, coffee at 50 cents, and other things in proportion.

THE Queen of the West mine, on Democrat mountain, Colorado, has been sold to parties in Burlington, Iowa, for \$100,000.

A TAX is proposed on gold and silver.

Mining in Trinity County.

A correspondent of the *Bulletin* writes from Indian creek, Trinity county, as follows:

Trinity county is not far, if any, behind the other counties in improved hydraulic machinery. Perhaps the most completely rigged claim here is James Johnston's. It consists of about 100 acres, a bar on the south side of Indian creek, averaging in depth about 50 feet, and is over a mile in length, and 600 feet wide. There are two "giants" on this claim, one 11-inch outlet, with a 6-inch nozzle, and one 9-inch outlet, with a 4 $\frac{1}{2}$ -inch nozzle, supplied by a main trunk of 22-inch pipe, 600 feet long, which reaches the bedrock, where it divides into 11-inch and 15-inch pipe, running four or five hundred feet further. There are two flumes, a 4-foot one for the larger giant, and a 3-foot one for the smaller one. They are lined with 8 $\frac{1}{2}$ -inch blocks, each flume carrying between two and three thousand inches of water. It requires two large ditches of the capacity of four and six feet width by three in depth to supply this claim with water, and even then he has to use two reservoirs, one of which is 600 feet long by 50 in width.

Smylie & Trotter's claim at Douglas City has a hydraulic giant, with a 15-inch outlet, 8-inch nozzle, and 22-inch pipe. This machine has been in use two years. This is a good claim. They have been running night and day, having made two clean-ups, amounting to about \$10,000. Their flumes are four feet wide and three feet deep, lined with 8-inch blocks.

Marshall & Mason's claim at Union Hill has two little giants—size, No. 1. On this claim they have been running tunnels for about a year. Commencing at the Trinity river, they run the main one about a thousand feet, from which they run branch tunnels in different directions. Some of the branches are as much as 50 feet beneath the surface of the channel bedrock, from which they raise shafts to the bottom of the gravel, through which, when the surface is worked off, they sluice. A few days ago, in one of the branch tunnels, they struck a new channel about 40 feet wide with perpendicular walls 10 or 12 feet high, and which, they say, prospects throughout from \$1 to \$1.25 to the pan. Mr. Trotter, our ex-County Clerk, who owns a one-fourth interest in this mine also, says that he wouldn't give two hits for any one to insure him \$10,000 for his share of the dividends.

Weaverville is all life; everybody is resting and smiling; even the saloon keepers have ceased to stand in their doors to take the measure of strangers as they come up Main street, to see if there is a probability of their having a spare "piece" about them. There are some good claims here, among which may be mentioned those of our ex-legislator McMurry and Davison & Jenkins. The former has a giant machine, and pays well. The latter is in the bed of Weaver creek, and has a flume that takes the water of all the claims in Weaver basin, being 16 feet in width, with 9-foot frames, on which are 6 foot sides, and is over half a mile in length. It takes 42,240 superficial square feet of blocks to line it, which cost at the ordinary price of \$3 per 12 feet of a 3-foot flume, \$3,500. Mr. Davison has a sawmill, and furnishes his own and other claims with blocks and lumber.

AN EXPLODED CONTRACT.—On Friday last Judge Wheeler granted the motion for transferring the case of Joseph Haffenecker against Donald Bruce to the United States Circuit Court. The suit was brought to recover \$3,000 alleged to be due on a contract for the manufacture and sale of a certain explosive compound. Bruce alleges that the compound was known and rejected many years ago in Europe, and is so dangerous withal that it cannot be put to any practical use in mining. It was ruled that a State court does not possess any jurisdiction to examine into the validity of letters patent, and that, therefore, in order to meet the points of the dispute in the present case it was only just and proper that the United States Circuit Court should deal with it.

THE location of the Lick Observatory and telescope on the summit of Mount Hamilton, and the construction of a carriage road thereto from San Jose, has stirred up the Stanislaus county people to building a road from the west side of the San Joaquin valley to the summit, thus making a direct route to the Yosemite valley, without the long detour now necessary. The Stanislaus county finances are now so low that the county can do nothing about it for some time to come, but it is expected that a private company will soon start the work.

A NOC fell into the hulkhead which supplies the water for the hydraulic pipe in the Blue Tent Consolidated mining company's diggings at Nevada City, the other day, and was forced through the pipe and out of a five-inch nozzle, bringing up against the bank several hundred feet distant in a very demoralized condition.

DAN DE QUILLE, of the *Virginia Enterprise*, for whose forthcoming book much inquiry has recently been made, has received a telegram from Mark Twain stating that it is nearly ready for delivery, and that canvassers will soon be bent in the field. The name of the book is *The Bonanza*.

A STEAM HAMMER weighing 13,000 pounds has arrived in Virginia City for the Savage mine. It will be set up in the company's machine shop.

Mining Then and Now.

The Grass Valley Union, reminded of old times by the late severe storm, indulges in some reflections, and gives a little good advice, as follows:

Twenty-one years ago this winter the rains were welcome, because then the "dry diggings" wanted water, and the miners on Wolf creek wanted water; the Jenny Lind diggings awaited water for washing purposes, and Alta hill had to have water in order to clean up the gravel that was piled above ground before it could turn out the gold dust. In those old days men used to go out after a heavy storm and find great big nuggets of gold. In those days the Grass Valley miner, clothed in rubber, did not lose a minute of the day while the rains fell. That old time miner did not stay around a stove and play pedro. He worked. Now the miner does not risk his health in pursuit of gold. He has more philosophy. He now knows that the chief end of man is not to accumulate the yellow dross (it is powerful to have even now), but that a pleasurable afternoon can be spent while the full sluice heads of water are running to waste. One reason of this reform is that there is not now as much gold in the gravel as there used to be. Hence the sweep of pedro for sluicing. Pedro pays better just now. In the old days, when the gold had not been all taken from the grass roots, the finding of big diggings was the more exciting sport. But our boys ought to go out and find some ledges. Those ledges are going to pay, and they furnish the sinews of war wherewith to fight pedro in the future, or they may do better still and give the means for travel and cultivation. Locate ledges in spite of storms.

NEW GALENA BELT.—A correspondent from Ellsworth, Nye county, Nev., announces the discovery of a rich galena belt, eight miles west of that town, which runs north and south, and is 40 feet in width. Three locations of 1,500 feet each have been made, the middle of which, called the "Illinois," is reported to have turned out \$4,650 from 10 tons, bringing to the owners at the mine a net profit of \$310 per ton. Ore assaying as high as \$1,000 is reported in sight, and the whole belt is said to assay 65 per cent. of silver and 35 per cent. of lead to the ton. Mr. McGee, of Tyho reputation, is reported to have offered \$70,000 coin for a portion of the claim. The ore is in easy working ground, with plenty of wood and water at hand. Several other mines are being opened up in that neighborhood, and a 20-stamp mill will soon be a necessity.

THE MINERS' UNION AT EUREKA.—Superintendent Rickard publishes a letter in the *Eureka Sentinel* of the 15th, denying that he had, in behalf of the Richmond company, yielded to the demands of the Miners' union. He says, on the contrary, that after hearing from representatives of the union that they would, in future, not allow non-union men to work in the mine, nor contracts to be given for taking out ore, he came to the conclusion that it would be better to shut down the mine than to submit to any such dictation. Mr. Ratcliffe, president of the Miners' union, desired it to be understood that for the remainder of this month and for 30 days thereafter, they can employ whom they please; but at the expiration of that time all miners will be required either to become members of the union or quit work.

A LARGE party of mounted Indians made an attack upon the suburbs of Custer City in the Black hills, March 4th, driving off all the loose horses grazing in that vicinity, and at the same time made a dash at an emigrant train, nine miles below, killing one man—Charles Holt, of Sioux City. A party of 60 well armed men at once collected at Custer, and went in pursuit of the savages, but with what result is not yet known.

UNIONVILLE ITEMS.—The Arizona mill, which has been shut down for some time, in consequence of the scarcity of fuel, will start up next Monday. A rich strike, one of the old time bonanzas, is reported to have been made in the Arizona mine. The old camp, like many others, has been quite dull this winter, but is recuperating and promises to be as lively as ever next summer.—*Silver State.*

THE machinery for a wooden bowl factory is now in Seattle, and will probably soon be put in use. It is intended to erect a building near Nation's foundry, and have this machinery in it and in use about a month. The bowls will be made of maple and alder, six from a block, six at a time, six in eight minutes and six of different sizes. This will be the only factory of the sort on the coast.

THE widow of the late Sandy Bowers predicts that Reno, Nevada, is to be the most important city on this coast, excepting San Francisco. Very rich mines are to be discovered there. The Nevada Journal says she predicted the late discovery of quicksilver.

SILVER CITY, Idaho, is excited over the discovery on Siuker creek, seven miles from town, of a large mica ledge of excellent quality, some of the plates taken out being from four inches to two feet cross.

THE military authorities at Fort Laramie allow emigrants to go on to the Black hills without molestation, if organized in parties of 20 or more and properly armed.

USEFUL INFORMATION.

Mending Tin-Ware.

Faith Rochester, in the *Agriculturist*, describes a method of soldering which we have long used, and can recommend it to all our readers. It is essentially as follows:—Get an ounce of muriatic acid, put it into an old tea-cup or bowl, and throw in a few small pieces of zinc, such as you can pick up at any tinner's. After it has ceased to effervesce, turn into a bottle and use a small stick to apply the liquid to the tin. Scrape the tin clean and bright around the place to be mended, rub some of the liquid on with the stick, lay on a piece of solder, and hold it over a lighted candle till it melts, and the job is done.

We use a small soldering iron, and much prefer it to the candle plan. A soldering iron can had for 25 cents that will answer every purpose; 10 cents' worth of solder will last a year in an ordinary family, and the muriatic acid will not cost any more. What a tinner or traveling tinker would charge for a single job of mending will buy a complete outfit, and then you are done with the annoyance of leaking vessels, or being compelled to work without them, at a great disadvantage. With farmers who live some distance from town, the soldering outfit is one of the greatest conveniences—with us it is indispensable. We keep the iron, solder and fluid (the latter well corked except when in use) in a box by themselves, on a shelf out of the reach of children. The muriatic acid is a very powerful corrosive agent, and must be handled with extreme care. Children must not be permitted to get hold of it. Several years ago we bought a bottle of soldering fluid of a man who was traveling around selling it—at 50 cents per bottle. Not long afterwards we got hold of the above recipe for making precisely the same thing—at a cost of 10 cents instead of 50.

RUSSIAN MANUFACTURES.—The Russian edge tools differ from those of other countries in some peculiar respects. The common spade, for instance, is made chiefly of wood and simply tipped with iron; it is of small size, rounded at the edge, and has a plain curved handle. The axe is much larger than that manufactured by other nations, and is used, too, for all kinds of carpenter's work—answering, in fact, as a plane, a hammer, and even as a saw, the last tool being rarely used by the Russian mechanic, for he can wield the axe more easily, and cut through thick logs of wood with incredible precision and rapidity. Samovars are a leading article of the Russian metal industry, these being a kind of tubular boiler, with little charcoal furnaces, and are used for making tea; the material is copper, which is almost exclusively used among the well-to-do classes for cooking utensils, tinware, hollow cast-iron vessels and pewter being but little in vogue. Horse-shoes are produced by hand at the rate of some 30,000,000 annually. Bell-making is carried on with especial success, the bells being remarkable for their immense size and richness of tone. Harness fittings of European pattern are made, but only in very limited quantities, those which are used upon Russian harness being of considerably different construction.

SUPERIORITY OF WOOD SCREWS OVER NAILS.—Most mechanics who work in wood do not appear to understand the eminent superiority of wood screws over brads and nails. In many places one screw is worth three or four nails. When one is securing cleats to batten doors or cleats to a wagon-box, nails are very unsuitable when compared with the efficiency of gimlet-pointed screws. Screws will hold two pieces of wood more rigidly than nails; and if the timber should shrink a trifle the screws can be turned up tight; whereas it is difficult, in most instances, to tighten up loose work with nails in all places where there is an unusual strain on the parts to be held together.

COW HAIR AS A SUBSTITUTE FOR WOOL.—There is now being manufactured in England a class of goods known variously as veloms, Ulster coatings, chinchillas, etc., alleged to be made of hair and vegetable fiber, without the admixture of wool in any shape. These goods are finding their way into the United States, and the custom house authorities are not a little puzzled as to where to place them, when scheduling them for duty. Testimony of experts was called in; but it was only another case in which "doctors disagreed." The solution of the problem has been made the duty of the National Academy of Sciences.

"It took that German savant just 14 years to make an egg and hatch the same, but it will take him just twice that long to convince us of the fact." Allowing that it is a fact, we fail to see the economy of the new method. Had the savant invested fifty cents in a motherly old hen, he could have had more eggs, a more numerous hen progeny, and something over to pay for the wear and tear of the hen.

RATS that live in granaries are said by a professional rat catcher not to be poisonous, while those that live on refuse meat inflict painful wounds. This is another argument in favor of the vegetarian theory, and every pious family should keep a granary.

An invention has just been patented by which the gas from coal stoves may be utilized for lighting the various apartments of a house.

Utilization of Cobwebs.

Cobwebs have been applied to various uses. The delicate cross-hairs in the telescopes of surveying instrument are fine webs taken from spiders, a species that are specially selected for their production of an excellent quality of this material. The spider, when caught, is made to spin his thread by teasing him from hand to hand, in case he is indisposed to furnish the article. The end is attached to a piece of wire, which is doubled into two parallel lengths, the distance apart exceeding a little the diameter of the instrument. As the spider hangs and descends from this, the web is wound upon it by turning the wire around. The coils are then gummed to the wire and kept for use as required. About a century ago, Boa of Languedoc succeeded in making a pair of gloves and a pair of stockings from the thread of the spider. They were very strong and a beautiful gray color. Other attempts of the same kind have been made; but Renumar, who was appointed by the Royal Academy to report on the subject, stated that the web of the spider was not equal to the silkworm, either in strength or luster. The cocoons of the latter weigh from three to four grains, so that 2,304 produce a pound of silk; but the eggs of the spider, when cleaned, do not weigh above the third part of a grain, so that a single silkworm can accomplish the work of 12 spiders.—*American Cyclopaedia*.

THE TINNING OF BRASS OR COPPER ARTICLES. Nearly all the known recipes for plating articles with tin are attended with the inconvenience of not giving the proportions of the substances to be employed for this operation. If, as is commonly done, very concentrated solutions are employed, tinning is not produced. If they are too diluted, the tinning is slight. Numerous experiments have proved that the following formula produces excellent results: Dissolve 10 grammes (about 6½ dwts.) of tartaric acid in a liter (about 1½ pint) of very soft distilled water; boil this solution, plunge in it the articles to be tinned, and add 10 grammes (about 6½ dwts.) of fine granulated zinc. This granulated zinc may be easily prepared by shaking fused zinc in a box coated with chalk. Then care must be taken to turn the articles to be tinned several times, and replace the water which evaporates. At the expiration of a short time the tinning commences, and the articles in the bath must be continually turned over till the required degree of tinning has been obtained.—*Le Technologiste*.

LEATHER BLACKING.—An excellent blacking for leather may be made thus: Dissolve 11 pounds of green vitriol and five pounds of tartaric acid in nine gallons of water. After the settling draw off the clear liquid; then boil 16 pounds of logwood with about 18 gallons of water and 11 gallons of the fluid. Let the boiled mixture stand for about eight days, pour it off from the sediment, dissolve in it two pounds grape sugar, and mix this liquid with the green vitriol solution. The blacking so obtained may be made still brighter by mixing the logwood decoction with four pounds of aniline black-blue before the addition of the vitriol. The application of the blacking is very simple. The leather is first well brushed with a solution of soda, or still better, with spirit of sal-ammoniac, in 25 times as much water, to get rid of the grease. The blacking is then applied with the proper brush for the purpose.—*Stummer's Ingenieur*.

WEAR AND TEAR OF RAILROAD TRAINS.—It is estimated that every time a train of cars of the average length stops, it costs in wear and tear of material and loss of power, fully 75 cents. This is what makes a conductor always look so cheerful when he hauls up at a flag station, in the middle of a snow storm, to take on a string of onions and a man with a dead-head pass.

GOOD HEALTH.

Toothache and its Remedy.

EDITORS PRESS:—While looking over your valuable paper this morning, my attention was attracted to an article headed, "Bicarbonate of Soda a Toothache Remedy," and, with your permission, I will say a few words through your paper in favor of this useful remedy, not with the intention of claiming anything for your correspondent, but to say that years of experience has convinced us that Dr. Buckwith's opinion is certainly correct. Having suffered many years with severe attacks of toothache I am happy to throw any light on the subject that I can.

About 15 years ago, while suffering severely from an attack of this kind, after trying everything I could hear of without any good effects, I resolved to try an application of cold water—as the aching was accompanied by a burning sensation—which I did by filling the mouth with cold water. In about one minute the pain was gone; but as soon as the tooth would get warm the pain would commence again. Then remembering that bicarbonate of soda was of a cooling nature, I determined to try it, and as the tooth was a mere shell I filled it with this article, which of course came directly in contact with the diseased nerve. The result—as quick as thought the pain was all gone, and as the taste produced was something like that which

we get by mixing different kinds of alkalies and acids together to make summer drinks, I inferred at once that the pain was caused by the acid saliva coming in contact with the nerve of the tooth. I have always used it since, and have recommended it to hundreds of others who have used it with the same results. There are two kinds of toothache—one of which, only, the soda will relieve. The desired application can be determined by taking first cold and then warm water in your mouth; to the one relieved by the cold water apply the soda, as directed; to the one relieved by the warm water apply oil of cloves, pain killer, camphor or some such hot & stimulating remedies.

Contra Costa Co., Cal.

A SUFFERER.

EXPANDING THE LUNGS.—Step out into the purest air you can find; stand perfectly erect, with the head well up and the shoulders back, and then fixing the lips as if you were going to whistle, draw the air, not through the nostrils, but through the lips, into the lungs. When the chest is about half full, gradually raise the arms, keeping them extended, with the palms of the hands down, as you suck in the air, so as to bring them over the head just as the lungs are quite full. Then drop the thumbs inward, and after gently forcing the arms backward and the chest open, reverse the process by which you draw your breath till the lungs are entirely empty. This process should be repeated immediately after bathing, and, also, several times through the day. It is impossible to describe to one who never tried it, the glorious sense of vigor which follows this exercise. It is the best expectorant in the world. We know a gentleman, the measure of whose chest had been increased by this means some three or four inches during as many months.—*Home Journal*.

CURE FOR DIPHTHERIA.—The ravages of diphtheria in Australia have been so extensive within the last few years, that the Government offered a large reward for any certain method of cure; and among other responses to this was one by Mr. Greathead, who at first kept his method a secret, but afterwards communicated it freely to the public. It is simply the use of sulphuric acid, of which four drops are diluted in three-fourths of a tumbler of water, to be administered to a grown person, and a smaller dose to children, at intervals not specified. The result is said to be a coagulation of the diphtheritic membrane and its ready removal by coughing. It is asserted that where the case is thus treated, and has not advanced to a nearly fatal termination, the patient recovered in almost every instance.

ADMINISTERING MEDICINE.—When a teaspoonful of any medicine is prescribed by a physician, it should be borne in mind that the quantity meant is equal in volume to 45 drops of pure water at 60 degrees Fah. It is a good plan to measure off this amount in water in a small wine-glass, and mark on the latter the exact height of the fluid. This will give an accurate and convenient standard for future use. Teaspoons vary so much in size that there is a very wide margin of difference in their containing capacity. It is well to remember, also, that four teaspoonfuls equal one tablespoonful or half a fluid ounce. A wineglassful means four tablespoonfuls, or two fluid ounces; and a teacupful, as directed by cookery books, indicates four fluid ounces or one gallon.

KEEPING THE HANDS SMOOTH.—A writer in the *American Grocer* says that glycerine is not used in the right way. She asserts that to preserve the smoothness and softness of the hands, keep a small bottle of glycerine near the place where you habitually wash them, and whenever you have finished washing, and before wiping them, put one or two drops of glycerine on the wet palm and rub the hands thoroughly with it as if it were soap, then dry lightly with a towel. Household work and bad weather will not prevent your skin from being smooth and soft, if this plan of using glycerine is followed.

The skins of fruit, especially grapes, are often swallowed with the vague notion that they promote digestion, or the idea that they prevent any bad effects from eating said fruit. No error can be more fatally absurd. Cases have occurred where such practices have been the cause of death, and that of the most excruciating nature. The skins of fruit contain no nourishing qualities, but are one of the most indigestible substances that can be swallowed. They pass the stomach without any change, although they cause excessive irritation, and frequently inflammation of the bowels.

BIRDS CARRYING CONTAGION.—The Elgin, England, *Courant* records the fact of a pigeon having been lately shot near the city which has been declared by veterinary surgeons and competent medical authorities to have been evidently affected by foot-and-mouth disease at the time of its death. The body of the unfortunate bird has, it is stated, been sent to the Veterinary department of the Privy Council office for examination, in the hope some new light may thereby be gained relating to the spread of this disease among cattle.

TROCHES.—Every one can make his own troches by following this recipe, given in the *Household*: One ounce pulverized cubebs, one ounce pulverized licorice, one ounce pulverized gum arabic, one-half pound pulverized sugar; just water enough to moisten; warm slightly, stirring constantly; roll thin, cut out with a thimble, and dry.

DOMESTIC ECONOMY.

RICK CROQUETS.—Bake a quarter of a pound of best rice in a pint of milk until well swelled and dry. While hot beat in the yolks of ten eggs, three ounces of sifted sugar and a little grated lemon peel, or any flavoring preferred. Spread this on a dish to the thickness of half an inch and let it remain until cold. Then put a few finely sifted bread crumbs on your hand; take as much of the rice as will heap a dessert spoon, put it on the crumbs in your hand and roll into the shape of an egg. Beat up an egg, white and yolk, dip the croquet into it, roll it in bread crumbs, put in the wire basket. Repeat this process until all your rice is used, then fry the croquets in plenty of boiling fat. Clarified drippings answer well for frying these croquets. Care, however, must be taken that the fat is the right temperature, which may be readily ascertained by plunging a piece of bread into the fat. If the bread browns instantly the fat is ready. Dip in your wire basket containing the croquets, move about gently in the fat, and when they acquire, as they should do in less than a minute, a golden color, they are done. Put them on white paper to absorb any fat clinging to them, sift sugar over and serve.

BAKED APPLE PUDDING.—Set a quart of milk over night, take off the cream in the morning, and heat your milk in a spider to a boiling point. Wet two dessert spoonfuls of corn starch in a little cold milk and stir into it, and continue stirring till it thickens. Set it off from the fire. Beat together two eggs and a half cup of white sugar; then pour your corn starch into this, stirring it together carefully, and add a teaspoonful of salt. Pare and slice thin six large pleasant apples; lay them into your pudding dish, pour the custard over them and bake for an hour, or until the pudding is tender. For sauce, add sugar, nutmeg, and a little extract to the cream. This is a very economical and delicious pudding.

A CLEANSING AND RENOVATING POLISH.—Take of olive oil one pound, of rectified oil of amber one pound, spirits of turpentine one pound, oil of lavender one ounce, tincture of alkanet root one half ounce. Saturate a piece of cotton batting with this polish, apply it to the wood, then, with soft and dry cotton rags, rub well and wipe off dry. This will make old furniture in private dwellings, or that which has been shop worn in waterworks, look as well as when first finished. The articles should be put into a jar or jug, well mixed, and afterward kept tightly corked. This is a valuable recipe.

PUMPKIN PRESERVES.—A writer who has tried it says to preserve pumpkin take seven pounds of pumpkin, five pounds of sugar, four lemons and two ounces of green ginger root. Cut the pumpkin in slices half an inch thick, in any desired form, square, round or diamond shape, and boil in the syrup till tender, then take up the pieces. Slice the lemon and ginger root very thin and scald them in a little clear water, after which add them to the syrup; boil the latter down until it is clear enough to keep without fermenting and then add the pumpkin to it.

TO CLEAN GARMENTS.—Wet a sponge in warm water and squeeze it out till dry; then sponge one place after another until all the garment has been cleansed. All the dust and soil will be absorbed by the sponge. But if the garment is very much soiled wash the sponge in clean water several times, squeezing it as dry as possible by wrapping it in a piece of black alpaca. This method of cleansing is more effectual than a hand brush, and many spots will disappear by the use of pure water.

RENOVATING BLACK KINS.—Ink and sweet oil mixed, two parts ink to one part oil, will also make a nice glossy blacking for glove kid boots. Prepare a bottle of it, and attach a small sponge to the cork, as is done in "liquid blacking." The same varnish touched on very gently to the white tips and seams of worn black kid gloves, will make a pair quite respectable for either traveling or shopping.

TO RENOVATE BLACK SILK.—Grate three or four large potatoes into water, and strain off the water after letting it come to a boil. Then put an old dark colored kid glove into it, and boil for ten minutes. Sponge over the breadths of the dress with the glove, and when damp enough to iron well, press on the wrong side with a flat iron not too hot, so silk scorches easily.

TO BAKE BEANS.—Prepare them as for stewing, and place them with a large quantity of water in a stone-ware pot in a hot oven. Let the oven cool somewhat after they begin to cook, and bake them from four to six hours rather slowly. Leave out meat and butter, and trim with cream and salt.

TAR SPOTS.—Butter will remove tar spots. Soap and water will afterward take out the grease stain.

TO REMOVE PAINT SPLASHED UPON WINDOW PANES, use a hot solution of soda and a soft flannel.

KEROSENE and powdered lime, whitening or wood ashes, will scour thus with the least trouble.

W. S. EWES.....SENIOR EDITOR.

DEWEY & CO., Publishers.

of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week, 1 month, 3 months, 1 year.
Per line.....25 .50 1.00 2.00
One-half inch.....1.00 3.00 7.50 24.00
One inch.....1.50 4.00 12.00 40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance.—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or wishing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

CHOICE VOLUMES.—We have a full new set of Scribner's Monthly—ten volumes—well bound, for sale at this office. Price, \$2 per volume.

In remitting cash to this office, do not send us checks on interior banks, as we generally have to return them by express for collection.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, March 25, 1876

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Glacial Epoch; Saw Milling; California and the Centennial; Our Mining Engineers; Chinese Miners; The New Almaden Mines; The Mining Detritus Question; Brown's Uniquitous Eod-hake Shoes; Academy of Sciences; Gems and Precious Stones.

ILLUSTRATIONS.—Roth's Saw File Guide, 193. Brown's Uniquitous End-Sheke Shoe, 201.

SCIENTIFIC PROGRESS.—New Industrial Applications of Salicylic Acid; Geographical Progress in 1875; The New Metal, Gallium, and its Salts; Penetration of Roots in Rock; Scientific Researches in the Gasian Sea; An Interesting Experiment, 195.

MECHANICAL PROGRESS.—A New Source of Power; Invention Relating to Car Wheels; American Steel; Dynamite Operations at Blast Furnaces; Beam End Protector; Gas Fixtures; Locomotives without Steam Domes; Parson's Manganese Bronze; A Novel Piece of Drill Work; New Telegraph Invention; Nihilism as Fuel; Comparative Cost of Steam Power, 191.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 196.

MINING SUMMARY from various counties in California, Nevada, Arizona, Idaho, Montana and Utah, 197.

USEFUL INFORMATION.—Mending Tin Ware; Russian Manufacture; Superiority of Wood Screws over Nail; Cow Hair as a Substitute for Wool; Utilization of Cowhairs; The Tinning of Brass; Copper Articles; Leather Blacking; Wear and Tear of Railroad Trains, 199.

GOOD HEALTH.—Toothache and its Remedy; Expanding the Lungs; Cure for Diphtheria; Administering Medicine; Kissing the Head Smooth; Birds Carrying Contagion; Cures, 199.

DOMESTIC ECONOMY.—Rice Croquets; Baked Apple Pudding; A Cleansing and Renovating Polish; Pumpkin Preserves; To Clean Garments; Renovating Black Kicks, 199.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 201 and other pages. MISCELLANEOUS ARTICLES.—Heat and Mechanical Force; The Contract System of Mining; From the Black Hills; Japanese Gold; The Production of Arsenic in Copper Mines; Prospecting for Sulphur at Steamboat Springs, 194. The Uses of Aluminum; The University's Needs; The Miners' Rights; Ten Millions in Silver; Mining in Trinity County; An Exploded Contract; Mining Then and Now; New Glens Belt; The Miners' Union at Eureka; Unlabeled Items, 198. The Government and the Black Hills; The White Pine Tunnel, 202. A Mica Bonanza; The Mines of Nevada, 206.

NEW ADVERTISEMENTS.

Mariposa Land and Mining Co.—Sale; Eureka Stone Manufacturing Co.—Assessments; Stockholders Meeting; Eureka Stone Manufacturing Co.

In the Consolidated Virginia mine there is no prospecting being done at this time, nor is there likely to be any until the C. & C. shaft is sunk to a sufficient depth to drift to and open the 1600-ft level. This will not probably be accomplished until late in the summer, as the shaft will have to be sunk to a depth of 1,400 feet or over before commencing to drift.

MR. FRYER, of "Fryer process" fame, is in town. We are promised a description of the whole process at a very early date.

The crowded state of our columns prevents us publishing several articles of interest this week.

We will answer the queries of several correspondents on the subject of "Tellurium" next week.

An inquiry on the subject of quicksilver mining will be answered in our next issue.

Our Mining Engineers.

In last week's issue we gave the details of the arrangements made for entertaining mining engineers from abroad who come to America to the Centennial exhibition. It is greatly to be hoped that the results of this general conference of mining engineers will be not only to elicit information of value to the mining community, but that it will also establish among the mining engineers of America more of an *esprit du corps* than now exists. There is, perhaps, no class in the United States which exhibits so little tendency to affiliation as the mining engineers. We speak more particularly of those on this coast, although we understand that the peculiarity is only a degree less marked elsewhere. Among us the mining engineers seem to have little in common. They are employed by this one or that one, make their reports to their employers, and keep their knowledge strictly to themselves. Of course if they are paid for a report no one expects them to divulge its secrets; but there are many matters of general interest which it would violate no honorable principles to make public, and which would be of value to the mining community.

Our mining engineers have abundant opportunity for observation, and an immense field to go over, but whatever they glean they keep for themselves. Metallurgical secrets are jealously guarded from professional brethren, and nothing is given up for the common good. Few of them—we may say none of them—ever write a line for the public prints, or turn aside in the slightest degree to prevent mistakes being made, which a word from them might obviate. We never hear any hints from our mining engineers as to improvements which could be made in metallurgical or mining operations, or do we ever hear of one offering any advice which is not paid for, and paid for well. All with whom we have ever conversed on this subject confess that there is a lack of *esprit du corps* among them. There seems to be a sort of jealousy or something very like it which pervades their intercourse. When one makes a report which by any means becomes public, the others pick it to pieces and find all they can to condemn. If one makes a blunder in a report, and subsequent explorations prove the incorrectness of his theories, all the others remember that particular report, and ignore others in which he was more fortunate in his conclusions.

Several times has an attempt been made to organize a society of mining engineers in this city, but this same spirit has thwarted the efforts of those who in good faith were trying to break up prejudice among their professional brethren and establish more amicable relations. A society came near being organized this winter, but no agreement could be consummated which would suit everybody as to the meetings and the manner in which they should be conducted. Some were for social informal gatherings where those in the field could impart to the others results of recent investigations, while others preferred a perfectly organized society, full set of officers, formal reading of papers, etc. Some were for forming an engineering section of the California Academy of Sciences and some for an independent society.

Over these questions there was such a difference of opinion that part would not join or lend aid or support, except to a formal society; while others would do nothing unless the meetings were informal, and partook of a more social character. Several meetings were held to settle the questions, and it was finally agreed—no, not agreed, but decided—that they should join in the Academy of Sciences and form an engineering section, as is the custom in other countries with similar societies. And in accordance with this resolution a number have joined the Academy, but a still larger number did not join. Whether an independent society will be formed or not, we do not know, but the "social" part of the crowd were firmly resolved to preserve the social features, to do which another society will have to be organized.

All this is much to be regretted. The proceedings of no other society on this coast would be read with more interest than those of the mining engineers; but the society should not be made up of any chosen few, but should constitute a body in which all the mining engineers of the coast have a voice. There are some who are eminent in their profession, who now turn a cold shoulder to others who perhaps have equal ability but less chance to display it. These more humble gentlemen naturally stand on their dignity as to their professional rights, and are perhaps unwilling to concede as much as they should. There are still others calling themselves mining engineers, whom both of the classes mentioned ignore entirely.

There is no doubt in the world that a good many assume the title of "mining engineer" without proper authority, and without even the knowledge or intelligence to carry out the assumed character. It would be to the advantage of the mining community to know these pretenders by name, but they have no means of finding out. If a society were organized on a proper basis, it would give a professional standing to its members which no prudent man would fail to avail himself of. Once established it could keep without the pale of recognition those whose merits did not equal their pretensions, and would soon rid the profession of persons who bring it into disrepute. With this would come emulation among the members to preserve the good name of the society and the

dignity of its proceedings, an *esprit du corps*, which is now wanting, a zeal for original investigation, a desire for the dissemination of information of value to the mining community, and a more healthy congenial feeling than now exists. Try it, gentlemen! Be less reserved in your communications with each other, and give the world a chance to know that there are as smart and intelligent a set of mining engineers on the Pacific coast as can be found elsewhere.

The New Almaden Mines.

The quicksilver mines and reduction works of New Almaden are 15 miles south of the city of San Jose, Santa Clara county, California, in the Santa Cruz mountains, at an elevation of 1,700 feet above the sea.

These mines were first worked for quicksilver in 1845, but the operations were on a small scale, and no record exists earlier than 1850. They have been, and are now, the most productive quicksilver mines in the world, excepting only the mines of Almaden in Spain. They are developed to a depth of 1,300 feet, and the workings extend horizontally, somewhat in the shape of the letter Y.

Between 500 and 600 men find steady employment—the work being actively prosecuted throughout the year. From the 1st of January, 1864, to the 31st of December, 1875, the number of feet of drifting and sinking on the mines of the company, as shown by the records, amounted to 129,724 feet, or 26.24 miles, at a cost of \$1,000,000. This does not include the excavations made in extracting ore during the period named, nor any expense for the same.

In 1875 there were used in the mines 2,361 kegs of black powder (25 pounds each), and 9,350 pounds of giant and hercules powder—the rock in most cases requiring to be drilled and blasted. At the close of the same year, about five miles of railroad, underground, were in operation, and over 2,000 drills were in active use.

The reduction works consist of nine furnaces, and include the most improved methods for working quicksilver ores. When the present improvements are finished, they may be considered as most complete and perfect in every respect.

The total product of all the mines on the company's property up to December, 1875, was 606,453 flasks of quicksilver, of 76½ pounds each, or 46,393,654½ pounds. The average percentage of the ore of the New Almaden for 23 years and 3 months is 14.58. The highest percentage for any year was in 1850-51, when it averaged 36.74 per cent.; the lowest was in 1874, when it was 4.29 per cent. The mines are now in a prosperous condition.

Chinese Miners.

In several places in the interior trouble is brewing between white and Chinese miners, and more difficulty is apprehended. The most curious way of getting ahead of the Chinamen that we have heard of is that adopted recently. It is said that the miners at Sweetland and all along between that place and French Corral, are actively engaged in forming a Miner's League, the object of which is to compel men that employ Chinese labor to pay the same wages per diem as white men receive for the same kind of work. This is assuredly a queer way of treating the question, and at least poses the merit of novelty. The San Juan Times, (Nevada county) in speaking of this subject says: We interviewed Judge Bell, superintendent of the Milton mines, a few days ago, and asked, among other things, "why he did not employ white labor instead of Chinese labor." He answered that the mines at present could not afford him to work white labor. He said the expenses of his company were so heavy that he could hardly make both ends meet with cheap labor; that if white labor was employed the mines would run behind and would soon force him to stop work. He said also that he would employ all white boys who desire to work, and pay them Chinese wages until such times as they may be able to earn more. He thinks there are a host of white boys who are being brought up in idleness that would make good men if they had a chance, and he proposes to give them a chance in his mines. He told us that he was ready to receive all who might come. All he asks is, that they will work and earn something for themselves. If there are any boys in this place who feel like earning their own living, here is a chance for them to do so.

CALIFORNIA GIANT MILL.—We are informed that the Boston mining company, A. P. Bacon, president, and James Brady, superintendent, whose mine is located at Mokelumne Hill, have just purchased and shipped a Cowles California Giant, quartz mill, such as we have briefly described in a recent issue. An experimental mill made of wood of this kind was put on the Alabama mine, near Jamestown, which is now doing good work, though not more than one-half the size of the new improved iron mill. Another mill of the improved pattern has also just been sold to the Oliver mining company, at Grey Eagle in El Dorado county. These mills are something like the Chilean mills in principle, but altogether different in construction. We will give the results of the work done by this mill as soon as it gets in good working order.

THE Lake Democrat says it is reported that John Parrott will take \$100,000 stock in a railroad to Lower Lake.

The Mining Detritus Question.

This very important question, which has been pretty thoroughly discussed this winter since legislative attention has been called to it, will have to be settled by a Federal commission, which will probably consist of competent government engineers. We have published in full the resolutions, reports of committees and memorials on this subject since discussion on it first commenced, and this week give the result of the vote in the Assembly.

We gave in our issue of March 18th the Mining Committee's report on the question, with the memorial to Congress, and in our issue of March 11th gave the Agricultural Committee's report on the same subject. The Assembly voted on the question on Wednesday of this week and decided by a very close vote to adopt the report of the latter committee.

Berry, the author of the bill, made a long speech in its favor, and it was then agreed to deal with the concurrent resolutions on the subject before disposing of the bill. Considerable wrangling ensued on a motion by Carpenter to postpone the whole subject-matter until Thursday, and another by Keddick to postpone the bill and take up the resolutions now. The latter motion prevailed.

Carpenter then moved the adoption of the resolution of the Committee on Mines in place of that of the Committee on Agriculture and the series of resolutions introduced early in the session by Berry. Carpenter said he was not prepared to vote for any resolution which said in so many words that the rivers and bays of this State are being filled up by the detritus, tailings, slickens, or whatever it was called, that came from the hydraulic mines. He did not believe it necessary for the purpose of the resolution to make such a statement. He did not believe it was wholly true, and argued that the facts would compel him to vote for the resolution of the Committee on Mines in preference to that of the Committee on Agriculture.

In the speech which he made against the foregoing memorial, Speaker Carpenter quoted statistics to prove that the Sacramento river carries less earthy matter in suspension than the Mississippi, the Ganges, the Nile and the Po. The last mentioned river carries nearly seven times as much. These rivers are all navigable in spite of the vast amount of earthy material transported by them. He read from a statement furnished him as an answer to T. J. Arnold's article on San Francisco harbor. This statement contained the following opinion on the filling up of Suisun bay: "If the Sacramento at Sacramento, draining less than one-third the entire drainage area of Suisun bay, carries by weight one to 1,000 of earth to water, it is safe to say that the entire water coming into Suisun bay will not average more than one to 1,500 by weight, or by bulk one to 3,000, and which is certainly an outside estimate. The average rainfall of the 54,000 square miles which drain into Suisun bay is about two feet, of which not over one-fourth finds its way into the bay, being say one-half foot, or a body of water one foot deep over 27,000 square miles. Now, we will assume that each 3,000 feet contains one foot of solid earth; hence, dividing 27,000 by 3,000 we have one square mile filled each year nine feet. In addition to the earth suspended in the water, there is also a certain amount of material being carried along the bottom of the stream by the force of the current; for this we will add 10 per cent. (same proportion used by Arnold), and we have then as a result one square mile filled each year to a depth of 10 feet instead of 41 feet, as erroneously stated by Arnold. A large part of this deposit of sediment is placed upon the lands between high and low tides, a fact which Arnold neglects in his estimate. From foregoing estimates it is safe to say that it will be 100 years before Suisun bay is filled up, as Mr. Arnold predicts. Even then the Sacramento and San Joaquin rivers will continue to have a navigable channel through the low lands now in the course of formation, and their navigability will not in the least be injured. When Suisun bay is thus filled in a century from this, the State will have added to its productive area from 40,000 to 50,000 acres of land of a fertility not to be excelled anywhere. Hence this slow filling up of Suisun bay will end in the great ultimate advantage of the State. The Sacramento mill is reclaiming for us slowly what otherwise would cost us millions of dollars to reclaim by artificial means." Mr. Clunie asked whose figures these were and it transpired that they were the calculation of J. Hamilton Smith, Jr., a gentleman well known as one of the most accomplished hydraulic engineers in the State, and superintendent of the largest gravel mine in California.

After Mr. Carpenter's speech Clunie followed for the agriculturists, and after him Blackwell for the miners. The previous question was suspended, and the resolutions of the Agricultural Committee were adopted as a substitute for the original, by the following vote: Ayes—Abbott, Bagge, Barber, Berry, Briggs, Bradley, Burbank, Carter, Clarks, Coffey, Collins, Clunie, Dixon, Hart, Hayne, Henshaw, Jameson, Kennedy, Lambourne, Lammers, Orton, Patterson of Kern, Patterson of San Joaquin, Preston, Quigley, Rankin, Rice, Ruggles, Sargent, Saverkrup, Swan, and Watkins—32.

Noes—Birney, Blackwell, Blue, Brieland, Broderick, Chapman, Carnwell, Covington, Crutcher, Donlap, Garrettson, Giffen, Griswold, Harding, Jones, Koutz, McInerney, McCarthy, Murphy of Del Norte, Murphy of San Fran-

cisco. Nott, O'Connell, Pullen, Ruisch, Rsd dick, Roberts, Samuels, Wilcox, Young and Mr. Speaker—31. The substitute was then ordered to engrossment by a vote of 33 to 31.

The memorial ordered to engrossment sets forth—First, That the detritus discharged from the hydraulic mines located upon the headwaters of the Sacramento, Feather, Yuba and Bear rivers, all of which flow into the bay of San Francisco, is having the effect of filling up all of those streams with sand and mountain debris, thereby threatening the villages and towns located on them with inundation and destruction of life and property, as well as obstructing to a great extent the navigation of the Sacramento and Feather rivers. Second, That it has been estimated by T. J. Arnold, engineer of the State Board of Harbor Commissioners, that at the rate the debris is now being washed down, it will take but 15 years to fill Suisun bay, but 31 years to complete the destruction of San Pablo bay; after which the bay of San Francisco proper is the only receptacle left for this entire debris washed from the mines. Third, That agricultural lands in the Sacramento valley are being covered up with unproductive mining debris, and there has already been destroyed over 75,000 acres, valued at \$6,350,000, with improvements on them worth fully as much more. Fourth, That at Sacramento and Marysville levees have been constructed at great cost, but that unless decided steps are taken for the relief of these cities, it will be impossible longer to resist the encroachments of the water and debris. The memorial, therefore, asks for the appointment of a federal commission, consisting of civil engineers, to ascertain as accurately as may be, the amount of detritus annually discharged from hydraulic mines into the Sacramento, Feather, Yuba, Bear, American and other rivers, and into the bays of the State. Also to inquire into the feasibility and probable cost of diverting and controlling said detritus so as to deposit the same upon swamp and overflowed lands, or upon the foothill lands, or retain the same in the mountains, or to suggest any other plan as will prevent injury to the valley lands, rivers or bays of the State, for the purpose of laying the same before Congress at a subsequent session.

This action of the Assembly may look like a decided triumph for the agriculturists, and if it should so prove it will be the fault of the miners alone, who have taken so little active interest in the matter. They probably are confident that their position is an unassailable one, as having priority of right; and they know the mines will continue to be worked one way or another. The Congressional commission, however, will take little notice of what has been said, but will start in from the bedrock and thoroughly investigate the whole thing. It is well known that in the tule lands the owners would gladly pay for the privilege of allowing this muddy water to settle on their lands occasionally if it could be controlled. As the government has given rights and titles to both miners and farmers, it may turn out that the government will have to foot the bills if any new system should have to be inaugurated. The question now, however, will be in proper hands, as intelligent, educated and unbiased government engineers will investigate; and those having conflicting interests should prepare themselves to abide by their decision, whatever it is. One thing sure, matters will have to remain as they are for some time to come.

Academy of Sciences.

A regular meeting of the California Academy of Sciences was held on Wednesday evening last. Ches. F. Hastings was elected a resident member. A large number of mineral specimens were received as donations to the cabinet from different persons.

Mr. F. Gruber, of Woodward's gardens, Curator of Ornithology of the Academy, read the first of a series of lectures on the subject of ornithology. The lectures are illustrated by specimens prepared by Mr. Gruber himself, over 40 vultures, eagles, falcons, hawks and owls being exhibited at the first lecture. Mr. Gruber's lectures are semi-scientific in character, and are well worth hearing, being by no means dry.

W. N. Lockington read a paper describing 18 new species of California crustacea.

A memorandum prepared by Prof. Davidson, showing his calculation of the solar eclipse of March 25th, 1876, for the United States coast survey station, Washington square, San Francisco, was read, as follows: Mean time of beginning, March 25th, 1h. 07m. and 07 seconds, A. M. First contact, 117° 18' to the west of the North point. First contact, 86° 40' to the right of the sun's vortex. Mean time of ending, March 25th, 1h. 51m. 15s. P. M. Last contact, 30° 36' to east of North point. Last contact, 21° 00' to right of the sun's vortex. Duration of the eclipse, 2 hours, 44 minutes, and 8 seconds. Magnitude, 9.4 digits.

LATEST reports from the Yellowstone region shows that serious trouble is likely to result from the rush to the Black hills. The Sioux, Blackfeet and Apsinabones have had many pipe smoking lately, and rumors of conferences of the Sioux with the other tribes are of daily occurrence.

Two men were buried up in a tunnel of the Menzantine mine, near Virginia City, on Friday last, by a cave, and remained there 12 hours before they could be dug out.

Brown's Undulating End-Shake Shoe.

A Laid and Important Improvement in Grain Separators.

We illustrate on this page a very valuable improvement for grain separators, invented by N. M. Brown, of Pescadero, Cal. It has been in use about two years, and has proven superior to the ordinary end-shake shoe, because the invention combines an undulating motion with the end-shake, thus making the operation of cleaning more positive. It always keeps itself clean, is simple and easily put in any thrasher, and will not get out of order readily. It presents more cleaning surface than any other shoe in use; requires less time to set the machine, one stake (at the end of the tongue) being all that is necessary; runs smoother, lighter, and with less power than the side-shake; but most important of all, it will save and clean all the grain that any cylinder can thresh.

The riddle is constructed in two or more sections. Each section consists of a wooden frame which is of proper width to fit easily inside the separator frame. Across these frames are stretched parallel wires at a proper distance apart to form meshes or spaces between them of desired size. These sections are then connected together by means of hinges or other suitable loose jointed connections, so that the end of one screw will be below the other, being

BROWN'S UNDULATING END-SHAKE SHOE.

careful to have the ends of the sections at which the wires are secured to the bottom of the bottom side of the frame, standing in the same direction. These connected sections are then secured inside of the separator frame by suspending the extremity of one end section by means of link hangers from the side of the frame, while the extremity of the opposite section is supported by a rod, the ends of which pass through a slot in the sides of the frame. A shaft passes across the frame directly below the hinged end of the uppermost section, so as to support it, leaving the end of the lower section to hang by the connecting hinges. The shaft has one or more arms, which serve as lifters or cams for raising and lowering the hinged end of the sections or middle of the riddle. A crank wheel is secured to each end of the shaft, and a rod connects these cranks with the projecting ends of the rods, which supports the rear end of the riddle. Thus it will be seen that by turning the shaft, the riddle will be moved back and forth longitudinally, and at the same time its hinged middle portion will be moved up and down, so as to give the riddle an undulating motion. By hinging the end of one section below the end of the adjoining section, is provided a drop for the straw and grain, which loosens up the straw and allows the grain to pass through the riddle.

The farmers in California have had considerable experience with both end-shake and side-shake grain separators; but we believe that when properly regulated and adjusted the end-shake shoe has proven itself superior to all others. The ordinary end-shake shoe, first introduced, was uncertain and unsatisfactory in its action, and could not be relied upon. The Brown shoe is entirely independent of that nice adjustment so requisite to the ordinary end-shake. It combines two motions, one an undulating and the other an end-shake, and these motions render it so complete in its action that it never clogs and does its work perfectly. A good separator is a necessity where the farmer has any care about the quality of the grain he puts upon the market. We call the

attention of farmers and manufacturers to this shoe, believing that it possesses substantial merit. Mr. H. C. Brown, the proprietor of the patent, can be consulted or addressed at the office of Geo. Morrow & Co., 39 Clay street, San Francisco.

Gems and Precious Stones.

(Written for the Press by HENRY G. HANES.)

(Continued from last week.)

(11.) Phosphorescence. A mineral is said to be phosphorescent when it has the property of emitting light; some minerals become phosphorescent when rubbed together in the dark; some by scratching harder substances than themselves; others by percussion; others again by heat. Lime shows this property on being strongly heated before the blowpipe, the intensity of the light being greater than that of the blowpipe flame. This property of lime is taken advantage of in the drummond light.

To show phosphorescence by heat a piece of red iron should be taken into a dark room and the powdered mineral thrown upon it as soon as the temperature of the iron falls below visible redness.

Touch. Some minerals have a peculiar feeling when rubbed with the ends of the fingers. Soapstone or stasite for instance, feel greasy or unctuous; the powder of other minerals feels dry, rough or spongy. Certain gems and crystals are cold when touched by the tongue, others

General News Items.

COUNTERFEIT trade dollars are in circulation.

The training ship *Jamestown* will be ready to receive students in about a week.

KEYSEN, one of the Tweed ring in New York, has been taken to the lunatic asylum.

ENGLISH mechanics are moving in ways to be handsomely represented at the Centennial.

The President has nominated John M. Coghlan, of California, as Chief Justice of Utah.

GEN. SCHENCK declines to be interviewed in connection with the Emma mine, but intimates that he will vindicate his own conduct.

STEPS are being taken by the Board of Supervisors of this city, to call a public meeting and send a deputation to Congress on the Chinese immigration question.

PIPER, by authority of the Committee on Commerce, has reported for passage his bill to relinquish the Marine hospital property in San Francisco for use as a Sailors' Home.

THE announcement of the decision of the Supreme Court of the United States declaring the laws of California in regard to Chinese emigration null and void has produced a profound sensation in this community.

ROSENSTEIN, sentenced to be hanged for the murder of Sara Alexander, has been granted a stay of execution by Judge Brady, until the case is reviewed by the general term of the Supreme Court.

THE Senate Committee on Privilege and Elections, on the 17th inst., beg an investigation of the charge against Senator Spencer of Alabama, that he secured his election by corrupt means.

The Government and the Black Hills.

A bill has been reported from the Senate Committee on Indian Affairs for an agreement with the Sioux nation, etc. It is, with a few amendments, the measure introduced by Mr. Allison. It provides for the appointment by the President of five commissioners, of whom one shall be an army officer not of lower rank than a brigadier general; another shall be learned in the law, and another shall speak the Sioux language; whose duty will be to visit the various tribes of Sioux and endeavor to make an agreement with them for the absolute relinquishment of their title to the Black hills country in return for an agreement on the part of the Government to provide for their subsistence and support for a period not exceeding 10 years. The appropriations for the purpose are to be in addition to the sums stipulated for by the treaty of 1868. The bill also provides that all appropriations hereafter made for the subsistence of the Sioux nation shall be upon the condition that they will agree to relinquish the Black hills and cede the right of the United States to secure free access to them by wagon roads, etc. Also, that they will receive all their supplies from points near the Missouri river, as the Government may provide, and they will acquiesce in such methods as may be provided by law, or adopted by the President, to advance them in civilization and means of self-support.

THE WHITE PINE TUNNEL.—It seems, after all, says the *Eureka Sentinel*, that an attempt will be made to tunnel Treasure bill, in White Pine county. Some months ago we published an item setting forth that Major Henry had organized a company in the East for this purpose. A Burleigh drill and other machinery consigned to Major Henry at White Pine has just been received at the depot of the Eureka and Palisade railroad in Eureka. This would seem to indicate that active operations are to be inaugurated. The magnitude of the enterprise is not much less than that undertaken by Sutro, and the belief is justified that its successful completion will be of far greater benefit to the mining world. The opinion has always prevailed among mining men that untold mineral wealth lies locked deep down in the bowels of Treasure mountain. The projected tunnel is designed to pierce the mountain at a great depth in one of the most favorable localities. We wish Major Henry success, and hope he has a stiff company to back him in his stupendous undertaking.

ANDREW McPHERSON, superintendent of the Newark mill, in Condon canon, while returning home from Bullionville on Tuesday night met with an accident, resulting, it is supposed, in instant death. As near as can be ascertained, when a short distance from Bullionville, McPhereson attempted to make his horse jump a culvert that runs under the railroad at that point. The horse made the jump, a distance of about 14 feet, but fell on the landing, throwing McPhereson head-foremost to the frozen ground, breaking his skull. Deceased was about 38 years of age, and a native of Ohio.

PNEUMONIA is alarmingly epidemic in the vicinity of Fairplay, Colorado, and the miners are leaving by dozens, while some of the mines are entirely deserted.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL.

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his speciality. Price \$2.50 coin, or \$3 currency, postage free

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867. This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

BY OTHER AUTHORS.

The Quartz Operator's Hand-Book, by P. M. Randall. 1871. Revised and Enlarged Edition. Cloth bound, 175 pages. Price, \$2.

Sulphurets: What They Are, How Concentrated, How Assayed, and How Worked, with a Chapter on the Blow-Pipe Assay of Minerals. By Wm. M. Barstow, M. D.; 1867; cloth bound, 114 pages. Printed and sold by Dewey & Co. Price, \$1; postage free. The best written work, and most complete work on the subject treated.

ANY OTHER BOOKS DESIRED will be furnished at the most reasonable rates by DEWEY & CO., Mining and Scientific Press Office, S. F.

Office of the Marshal for the District of California, San Francisco, March 4th, 1876. To Messrs. A. T. Dewey & Co., of San Francisco and State of California, creditor of J. T. LITTLE, bankrupt:

You are hereby notified that a warrant in bankruptcy has been issued out of the District Court of the United States for the District of California against the estate of J. T. LITTLE of the city and county of San Francisco, adjudged bankrupt upon his own petition. That the payment of any debts and the delivery of any property belonging to said bankrupt, to him or for his use, and the transfer of any property by him, is forbidden by law. That a meeting of the creditors of said bankrupt, to wit: Henry Gassett & Co., or Gassett, Bullard & Co., Boston, Mass., \$—; Seth Bryan, Boston, \$—; Danforth & Son, Boston, \$—; Chas. Fitz, Orléans, Maine, \$—; Boller, Coloma, Calif., \$—; W. E. Lewis, unknown, \$33; Adams, Shinn & Co., S. F., \$147; H. P. McNevin, S. F., \$750; H. D. Bacon, S. F., \$83; F. W. Vale, S. F., \$200; J. D. P. Theller, S. F., \$—; A. J. Coshill, S. F., \$—; A. A. Snyder, S. F., \$233; Peter Dean, S. F., \$403; Little & Kaeding, S. F., \$120; Lusk & Co., S. F., \$70; Kohler, Chase & Co., S. F., \$250; Geo. Lander, S. F., \$400; G. O. McMullen, S. F., \$163; Miller & Hall, S. F., \$60; A. L. Bancroft & Co., S. F., \$100; A. T. Dewey & Co., S. F., \$83; Richard Ivers, S. F., \$500; A. T. Stevenson, S. F., \$70; John Malloy, S. F., \$112; W. G. Aiton, S. F., \$229; H. M. Bennett, S. F., \$310.57; Clark A. Sears, S. F., \$4,000; E. Schmidt, S. F., \$41.40; C. F. Cresswell, S. F., \$6; E. Post, S. F., \$1,177. Being the creditors upon the schedule filed with said bankrupt's petition, to prove his debts and choose one or more assignees of said estate, will be held at a court of bankruptcy, to be held on the 15th day of March, A. D. 1876, at 10:30 o'clock, A. M., at room No. 10, Court block, 635 Clay street, S. F., before J. M. GILBELL, Register. EDWIN P. MARSELLUS, U. S. Marshal as Messenger, District of California.

Our interest in the above (a note given for indebtedness about 1863,) is for sale cheap. DEWEY & CO.

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially machinery for mechanical ore concentration, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

F. MANSELL & CO.,

SIGN PAINTERS,

Bootmakers, Furniture Dealers,
Hatters, Jewelers,
Hotels, Piano Fortes,
Wine Merchants, Etc., Etc.

Machinery.

N. Seibert's Eureka Lubricators.

THE HIGHEST PREMIUM

Awarded by the Mechanics' Institute Fair, San Francisco, and State Fair, Sacramento, 1871.

These Lubricators are acknowledged by all engineers to be superior to any they have ever used; feed constantly by pressure of condensed steam, supplied by pipe A, regulated under the oil by valve J, and forced out through check valve and pipe B into the steam pipe C; it then becomes greasy steam, passes to all the valves and cylinder at every stroke of the engine; glass tube I indicates amount used per hour. Packing on rod and stems lasts longer, and the rings on the piston will not corrode. One pint of oil will last from three to six days, according to speed and size of engine; I, sliding gauge; K, valve to shut off when engine stops; H, F, valves to shut off in case of frost; steam does not enter the cup; it is always cool; warranted to give satisfaction. Patented February 14, 1871. Made by California Brass Works, 125 First street, S. F. 24v23

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and leading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

AUTOMATIC PUMP.

Raises water by compressed air to any height or distance. Windmill can be set at any distance from the well or spring if required to get a good exposure to the wind.

PURCHASERS please say advertised in Scientific Press.

THE TURBINE.

Simplest, Cheapest, and Most Durable.

The Inventor of the Dexter Windmill has made new and useful improvements in Windmills, patented March 16th, 1875, and now feels confident of having the SIMPLEST, CHEAPEST, MOST DURABLE, and

ONLY PERMANENT WINDMILL IN THE WORLD.

SIMPLEST, because it is less complicated; CHEAPEST, because it never needs repair, standing on a firm foundation; MOST DURABLE, because it is all under cover, and has less rigging to get out of order; ONLY PERMANENT, because the only Windmill in the world that has never been injured by storms. Hundreds of people, who have thought the Dexter perfect, will be glad to observe the SUPERIORITY OF THE TURBINE over all predecessors. Although much improved, the price of mills remain the same as formerly. Persons who study their own interest will investigate the TURBINE before purchasing any other.

Territory for sale outside of California, at reasonable rates and easy terms.

Mills built to order of the best material, and at the shortest notice, by Kinball Manufacturing Company, corner Fourth and Bryant streets, San Francisco. Any orders sent to their address will receive prompt attention.

For further information regarding Mills or Territory, send for New Circular. Address,

A Mica Bonanza.

This community is just now greatly excited over a mica ledge recently discovered and located by Frank Corbell and others, on Sinker creek, only about seven miles distant from town. It is said to be of an excellent quality and almost unlimited in quantity. We are informed that plates of it from four inches to two feet across can be obtained. If this be true, the boys are in possession of a bonanza of huge proportions than any quartz mine on the Pacific slope, the Consolidated Virginia not excepted. They are sinking on the ledge, and are said to be taking out blocks of solid mica of the size of a candle box. Mr. Corbell intends visiting the discovery, and will furnish us full particulars in regard to it when he returns.

In this connection a brief description of mica, its uses and value, will be of interest to our readers in general and to the people of this camp in particular at the present time: Mica is a mineral remarkable for its lamellar structure, and capable of being cleaved into plates of extreme thinness, many thousands of which are sometimes required to make the thickness of an inch. The most familiar form of mica is a constituent of granite, gneiss, mica, slate and some other kindred rocks. It is found both disseminated and in veins, and in many of the stratified rocks it is an incidental constituent derived from the destruction of the original formations to which it belonged. The colors of mica are various; the most common are silvery white, grayish, green, red and black. That found on Sinker is of a silvery white color. The principal mica mines in the world are in Siberia, Sweden, Norway, Canada and New Hampshire. Mica is used mostly for the doors of stoves and the sides of lanterns, for which it is well adapted by its transparency and refractory character. It is also employed as a substitute for window glass, and its toughness recommends it for this purpose on board vessels of war, in which the concussion from the discharge of guns would endanger the fracturing of glass. The value of good plates is about \$1 per pound.—*Quebec Avalanche*.

THE MINES OF NEVADA.—It is safe to say that at the present time the foundries of San Francisco are manufacturing for mines on the Comstock alone machinery which will cost \$2,000,000 or \$3,000,000. More than half the expenses of running these mines are left in that city. Indeed, there is not a mine worked here that is not a dividend paying mine to the men of San Francisco who sell goods or forge machinery. The best orders for goods are from Nevada; the highest machinery at the foundries is for Nevada; the biggest wire ropes are for Nevada; and so it goes, and so it has gone for a dozen years. The correct reasoning from all this is that mining—and silver mining at that—is the safest and surest business on this coast. And men with means should begin to see this and to reflect that while there is, so far as known, but one Comstock in the world, there are in Nevada a thousand undeveloped mines to be obtained cheaply, which, in the estimation of those best qualified to judge, hold ample returns for the little labor and money required to open them and reduce their ores. We have six or eight districts in mind full of these mines, and they are worth the careful attention of men who would make swift and sure fortunes.—*Virginia Enterprise*.

OVER \$1,400 was received at the Central Pacific ticket office at Reno, one day last week, for tickets to Cheyenne, bought by emigrants to the Black hills.

WATER TANKS of any capacity, made entirely by machinery. Material the best in use; construction not excelled. Attention, dispatch, satisfaction. Cost less than elsewhere.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the **best** ever made in **simplicity** of construction, economical use of power, **durability** and perfect adaptability for general uses, and we ask all persons interested to investigate **our title to this claim.** Saleeroome at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

BLAKE'S PATENT STEAM PUMP

Over 8,500 in Successful Use in the United States.

California Planers and Matchers, and Wood Working Machinery of all Kinds

California Planer and Matcher

Is gotten up from new patterns specially for this Coast. It has Cast Steel Slotted Cylinder Head, running in patent self-oiling boxes; will plane 24 inch wide and six inch thick, and tongue and groove 14 inch wide. Will make rustic and stick gutters, or heavy mouldings, etc., and is the best job machine ever built. We have always on hand these machines with or without under cutter head, also, a large assortment of Planing Mill Machinery.

SMITH'S PATENT MORTISERS,

Mortiser.

WITH LATE IMPORTANT IMPROVEMENTS.

Smith's Celebrated Molders.

We have four sizes of these Machines always on hand—"B," "C," "D" and "E,"—to work either three or four sides. Have slotted heads and all other improvements, and may be seen in any mill on the Coast. Prices reduced to 15 per cent. less than Eastern list. We have also, a large stock of all kinds of Planing Mill Machinery, such as Molders, Mortisers, Tenoners, Band and Jig Saws, etc. Send for our new Illustrated Catalogue. TREADWELL & CO.,

A New Motor.

We illustrate herewith a new motor—the Rider compression engine—which has just been introduced on this coast by Huntington, Hopkins & Co., Nos. 2 and 8 Bush street. As its name implies, the chief feature of this engine is the use of highly compressed cold air, the thorough heating thereof without change of volume, and its efficient expansion to a point to or below the pressure of the atmosphere, thereby completely utilizing all the force or mechanical effect possible.

The imperative demand for a motor possessing the elements of safety, economy, simplicity and durability, has called forth, during the past century, the best efforts of the most eminent engineers both of Europe and America, as evinced by the many varieties of motors at present in existence, operated by gas, atmospheric air, carbonic acid, ammonia, electricity, etc.; but till very recently, steam has been pre-eminent in utility, notwithstanding its danger, high rate of maintenance, and total unfitness in the hands of inexperienced persons. A careful examination of all the motors mentioned above, shows that atmospheric air is the only agent at all likely to successfully compete with steam, from its universal presence, its low capacity for heat, and its capability of producing great power when properly applied.

As may be seen by the annexed sectional engraving, Fig. 2, the engine consists essentially of a compression cylinder, A, and a power cylinder, B, with their respective pistons, C, D, and connections, and a regenerator, H. The lower portion of the compression cylinder, A, is kept cold by a current of water which circulates through the cooler, E, which surrounds the lower portion of the cylinder, while the lower portion of the power cylinder is kept hot by the action of the fire below the heater, F. The heating and also the cooling of the air is instantaneously effected by its alternate presentation to the surfaces of the heater and cooler in a thin annular sheet.

The compression piston, C, extends downward to the base of the engine, and is a trifle smaller than the interior of the cooler, E, thus leaving a thin space on all sides for the air to pass downward and become thoroughly cooled on its way to the bottom, and through which space it flows on its way back to the heater. The power piston, D, likewise extends downward into the heater, F, which presents to the action of the fire a narrow annulus all round the bottom. Within this heater is the telescope, G, which is a thin iron cylinder about one-fourth of an inch less in diameter than the interior of the heater. It is fitted to the interior of the power cylinder, and extends nearly to the bottom of the heater. Its office is to cause the air which flows from the compression cylinder to be presented in a thin sheet all round the interior surface of the heater, and particularly at the lower and hotter portion. By this means the air is thoroughly and rapidly heated.

The same air is used continuously, as there is neither influx nor escape, the air being merely shifted from one cylinder to another. Between the compression and power cylinders is situated the regenerator, H, composed of a number of thin plates slightly thickened at their edges, which, while affording a free passage to the air, subdivides it into thin sheets. It is so placed between the cylinders as to be traversed by the air in its passage each way between the hot and cold cylinders.

The other portions of the engine are readily

understood on the inspection of the engraving. The two pistons are attached directly to the cranks, I, I, by simple connecting rods, J, J, and all the movements of the various parts are uniform, being solely derived from regular, circular, and rectilinear motion; and as there is an entire absence of all complicated parts and the irregular intermittent impulses which characterize caloric engines, a high rate of speed and smooth action may be safely and easily obtained. K, K are the packings, which are in duplicate for each cylinder. The lower one has its lap downward to resist the escape of air below the piston, while the upper one has its lap upward to prevent the lubricating material from entering too freely into the cylinder. Between them is a patent relief ring to relieve the friction of the packings. L is a

Fig. 1.

THE RIDER COMPRESSION ENGINE.

simple check valve which supplies any light leakage of air which may occur.

The operation of the engine is briefly as follows: The compression piston, C, first compresses the cold air in the lower part of the compression cylinder, A, into about one-third its normal volume, when, by the advancing or upward motion of the power piston, D, and the completion of the down stroke of the compression piston, C, the air is transferred from the compression cylinder, A, through the regenerator, H, and into the heater, F, without appreciable change of volume. The result is a great increase of pressure corresponding to the increase of temperature, and this impels the power piston, D, up to the end of its stroke. The pressure still remaining in the power cylinder, and reacting on the compression piston, C, forces the latter upward till it reaches nearly to the top of its stroke, when, by the cooling of the charge of air, the pressure falls to its minimum, the power piston descends, and the compression again begins. In the meantime the heated air, in passing through the regenerator, has left the greater portion of its heat in the regenerator plates, to be picked up and utilized on the return of the air towards the heater. As

may be seen by Fig. 1, this pump is placed on the side of the cooler, and worked directly from the compression piston. All the water is passed directly through the cooler on its way to the tank or outlet.

These motors are valveless, noiseless, simple, and claimed to be absolutely safe; emit no heated air or unpleasant odor, as is the case with caloric engines; require no steam, cannot explode, do not increase risk of fire or cost of insurance, and can be operated by any one who can manage an ordinary stove.

They are well adapted for running all kinds of light machinery, printing establishments, etc., but are particularly valuable for pumping. One of these little six inch pumping engines (household size) has, we are informed, pumped for six months, without intermission or stoppage

will be started up in a few minutes should any one desire to examine it. The engines are made in several sizes, but are intended simply as small motors and are not made to compete with large steam engines. Those who have need of such a motor should not fail to examine this new machine, if only as a matter of interest.

Consolidation of Mining Companies.

The following is the full text of the bill passed by the Legislature and signed by the Governor with reference to the consolidation of mining companies:

An Act to add another Section to the Civil Code, Section 1. An additional section is added to the Civil Code, to be known as Section 361, and to read as follows: It shall be lawful for two or more corporations formed, or that may hereafter be formed, under the laws of this State, or mining purposes, which own or possess mining claims or lands adjoining each other, or lying in the same vicinity, to consolidate their capital stock, debts, property assets, and franchises in such manner and upon such terms as may be agreed upon by the respective Boards of Directors or Trustees of such companies so desiring to consolidate their interests; but no such consolidation shall take place without the written consent of the stockholders representing two-thirds of the capital stock of each company; and no such consolidation shall in any way relieve such companies, or the stockholders thereof, from any and all just liabilities; and in case of such consolidation, due notice of the same shall be given by advertising for one month in at least one newspaper in the county and State where the said mining property is situated, if there be one published therein, and also in one newspaper published in the county or city and county where the principal place of business of any of said companies shall be. And when said consolidation is completed, a certificate thereof, containing the manner and terms of said consolidation, shall be filed in the office of the County Clerk of the county in which the original certificate of incorporation of any of said companies shall be filed, and a copy thereof shall be filed in the office of the Secretary of State. Such certificate shall be signed by a majority of each Board of Trustees or Directors of the original companies; and it shall be their duty to call, within 30 days after

Fig. II.

the filing of such certificate, and after at least 10 days' public notice, a meeting of the stockholders of said companies so consolidated, to elect a Board of Trustees or Directors for the consolidated company for the year then next ensuing. The said certificate shall also contain all the requirements prescribed by section 296 of said Civil Code.

Seco. 2. This Act shall apply to all corporations formed under the laws of this State, whether formed under said Civil Code, or prior thereto.

Seco. 3. This Act shall take effect from and after its passage.

It is stated that a miner, named Munson recently found in the Globe mining district, Arizona, a solid mass of metallic silver ore lying on the surface of the ground, and weighing 2,200 pounds. A careful assay of it showed it to be almost a mass of pure silver, and worth at least \$20,000.

L. STANWOOD, an employee in the Gould & Curry mine and formerly foreman in the Savage, died suddenly at Virginia City on Thursday.

from derangement, each consecutive day of 10 hours, 10,000 gallons of water to a height of from 70 to 100 feet; and the engine required the services of an attendant less than 30 minutes each day, and consumed only 20 pounds of coal per day, thus pumping 2,000 gallons of water 100 feet high at a cost of only one cent. The engine is extremely simple. It has not a valve, spring, cam, lever, eccentric, or any loose or delicate part about it to get out of order. As to economy, we are told that it takes only from 20 to 30 pounds of coal to run a one-horse power engine for 10 hours. As there is no steam or danger of explosion no engineer is required, as it only needs some one to fire it occasionally and keep the bearings oiled.

These engines are well adapted for nurseries, breweries, tanneries, supplying fountains, irrigating, pumping water for cattle, etc. On farms they would be of great value as they require no care, and if neglected will simply stop work and not blow up, as the best steam boiler is apt to do if not taken care of. These engines can be put to a great variety of uses and are not at all complicated or expensive. One can be seen in operation at any time at the store of Huntington & Hopkins. If it is not running it

THE ENGINEER.

Carrying the Sea to Inland Cities.

Among the numerous engineering projects of the age, that of carrying the sea to inland cities is, perhaps, one of the most important. The first project of this kind was that by which Glasgow has been made the chief port of entry for Scotland. Situated about midway between the opposite coasts of that country, and on the banks of a river where formerly in some places only from two to three feet of water could be found, it was determined to deepen said river as to enable deep-water ships to come up to the city. Up to 1851 nearly \$10,000,000 had been spent in bringing about that result and in preparing the three miles of wharves and docks to accommodate the shipping. The enterprise has proven a most successful one and the outlay most profitable. The net income from these improvements is now about \$800,000 annually, to say nothing of the immense increase of population and wealth which they have brought to the city.

The Sea Coming up to Manchester.

And now, profiting by the example of Glasgow, the inhabitants of Manchester have also determined to bring the sea directly up to the looms of the great Cottonopolis of England. The promoters of the Manchester scheme propose to strengthen, deepen and widen the little river Irwell, by which that city stands, down to its junction with the Mersey, and to apply the same process to the latter river down to Liverpool, so that the grain-laden ships of California and the cotton ships of the Southern States can land their cargoes just where they are wanted for consumption and use.

This improvement, which will cost from \$17,000,000 to \$18,000,000, will provide a tidal canal for sea-going ships from Manchester to the sea, 33 miles in length, 200 feet in width and 22 to 25 feet in depth. The ships will be taken through the canal by tug, as they are now moved through the Suez canal.

With these projects in view, completed and contemplated, it cannot be many years ere we shall behold

The Sea Carried up to Stockton.

Which is destined to become one of the great inland cities of California. The importance of such a project, in view of the rapidly increasing commercial value of the great San Joaquin valley, will soon render it possible that such a work can be made a paying enterprise. There are no engineering difficulties in the way at all comparable to the deepening of the channels from either Glasgow or Manchester to the sea. The entire distance from Stockton to Venice, on the San Joaquin, whence a natural channel of efficient depth is continuous to the sea, is a perfect level, through every foot of which an ordinary steam dredger can be used.

In addition to the value of such a canal for commercial purposes it will also provide an increased channel capacity for carrying off floods, which will greatly aid in rendering practical and safe the numerous reclamation improvements now in progress all through that section of the State. The attention of capitalists has already been called to the need and importance of the enterprise, the cost of which will be small in comparison to the advantages which cannot fail to accrue from its realization; while, if we judge from the already completed work at Glasgow and the proposed enterprise at Manchester, it would offer a highly profitable investment for those who may supply the capital. The people of the San Joaquin valley already consider the construction of this proposed ship canal a mere matter of time. In all probability it will become the third engineering work of the kind in the history of modern commercial enterprise.

An American Engineer's Triumph.

Notwithstanding the many doubts thrown out against the probability of the success of Captain Eads' present efforts to open a deep ship channel through the mouth of the Mississippi by means of the jetty system, he has already accomplished far more than he had ever supposed possible at the present early stage of that enterprise. Recent dispatches from New Orleans announce the passage out to sea of well freighted cotton ships through the jetties at the South pass, which are as yet but partially constructed.

When the work of this jetty system was commenced a year or so ago, the bar on that pass had but seven feet of water upon it; now it has a depth of nearly twenty feet, a depth almost incredible to all but the engineers in charge. It seems from all advices, and from those business men from England and St. Louis, and other points interested in the success of this enterprise of Captain Eads, who have recently visited the jetties, that this masterly triumph of science over the continual obstructions created at the mouth of the Father of Waters is a fixed fact.

This recalls what Captain Eads spoke to the citizens of St. Louis at a recent banquet given by them in his honor when he was on the point

of starting on this enterprise of deepening the mouth of the Mississippi:

"If the profession of an engineer were not based upon exact science I might tremble for the result, in view of the immensity of the interests which are dependent on my success. But every atom that moves onward in the river from the moment it leaves its home amid the crystal springs or mountain snows, throughout the 1,500 leagues of its devotional pathway, until it is lost in the vast waters of the gulf, is controlled by laws as fixed and certain as those which direct the march of the heavenly spheres. Every phenomenon and apparent eccentricity of the river, its ebbing and depositing action, its carving banks, the formation of the bars at its mouth, the effect of the waves and tides of the sea upon its currents and deposits, are controlled by laws as immutable as the Creator, and the engineer needs only to be assured that he does not ignore the existence of any of these laws, to feel positively certain of the result he aims at. I therefore undertake the work with a faith based on the ever constant ordinances of God Himself."

Mechanical Engineering.

In mechanical engineering the past year has given us no remarkable novelty, although it has not been wholly barren of results. Renewed attempts have been made to introduce steam of very high pressure as a means of economizing fuel; and much ingenuity and energy have been, and will be, we fear, wasted in the pursuit of delusive advantages which never can be realized. All arguments in favor of high pressures are based on the assumption that by using them steam can be expanded a greater number of times than is possible when low pressures are employed, and that the more expensively steam is employed the further a given weight of the fluid may be made to go. Thus, for example, if a given weight of steam is used without expansion and does work represented by 1, by expanding it five times we can increase the work to about 2.5, and by expanding it a hundred times we could raise the duty to about 5.6. Now it is known that the gain due to expansion has nothing to do with the pressure; but the terminal pressure in a cylinder is settled by the amount of vacuum which can be obtained. The lowest practical terminal pressure is about five pounds on the square inch, but long before this point is reached the work done by the steam will be expended in overcoming frictional resistance; it will be useless work, in fact.

Experiments have proved that the lowest available terminal pressure is eight pounds to the square inch. It is obvious that if we attempt to expand steam, say 50 times, we must have an initial pressure, under the conditions, of eight times 20, or 160 pounds on the square inch. If a 30 fold expansion be attempted, then the initial pressure must be 240 pounds. It is, then, only because engineers attempt to employ great measures of expansion that high pressure steam is regarded with favor.

Up to a period of 10 or 12 years since, it was taken for granted that steam followed Mariott's law in expanding, and the coincidence for it is nothing more—of good diagrams with the operation of this law, lent additional strength to a pure delusion. Mr. Isherwood, of the United States, was the first to show in practice that when expanding in a steam engine, steam does not obey Mariott's law, and that its consumption increased enormously as the ratio of expansion is augmented. The influence of the condenser tells heavily against great measure of expansion. Watt's so-called separate condenser is only equivalent in its effects to what would have followed if he had lengthened the cylinder of a single-acting engine, and worked the piston at one end of this cylinder while he condensed at the other. In a word, the phrase "separate condenser" is a misnomer, and conveys a false impression.—*The Engineer.*

The American Institute of Mining Engineers.

This active and useful organization held its fourth regular annual session at Washington, during the last week in February. The organization was founded in 1871, and has rapidly increased in numbers and influence, until it has now about 600 names enrolled on its list of membership. It is the largest technical association in the United States. It is national in character, and is composed of the leading mining, civil and military engineers, metallurgists and chemists of the country.

A leading feature of the Institute, and one which will perhaps prove most valuable to the Pacific coast, is the regular appointment of active and capable committees to examine into doubtful metallurgical and mining questions. A report of one of these committees formed an important subject of consideration at the late meeting of the Institute—a committee co-operating with the United States Commission on Iron and Steel Tests.

This Institute intends, during the Centennial exhibition, to keep rooms open for the use of members, associates and others interested, at 1,123 Girard avenue, Philadelphia, and to have, beside this, their headquarters on the Centennial grounds. It will serve as a center of reunion and place of resort for all engineers, metallurgists, geologists, etc., and a general agency for the profession.

Horse Shoes.

A writer in the *Boston Commercial Bulletin* says: It would expand the eye of one of our old blacksmiths—the one, for instance, who hammered out the sparks "under the spreading chestnut tree"—could he behold the manner in which horse shoes are "turned out" in these latter days. Machinery, like some omnipotent monster, fashions, with equal ease, a pin or a steam engine, and outtrides itself into all branches of industry; but it did seem as if horse shoes were forever beyond its reach. But not so. Since it was a trifling matter for machinery to become a shoemaker for man, it isn't likely that it could long be kept from making shoes for man's faithful servant, the horse. Accordingly, we see to-day ingenious mechanisms that make more shoes in one hour than the village blacksmith could forge in a week, and, what is more, if the machine has any conscience or eye for reputation, it can make just as good shoes as these made by hand.

There is a prejudice against machine made shoes, however, from the fact that an inferior quality of iron may be, and often is, used. Shoes made by hand, on the contrary, must be of good iron, because in cutting the crease and punching the heel poor stock would be sure to crack; whereas, by machine process, the punching and creasing are done without much strain on the metal. The only security a man has for a good shoe is the trade mark of a house that warrant their goods; because it is to the interest of the blacksmith to put cheap shoes on a horse. He gets about \$2.50 for the job, shoes included. Hand made shoes cost about nine cents a pound and machine made six, consequently it is so much "in" if he uses the latter; not to mention the possibility of another job much sooner than should otherwise be needed.

Horse shoeing about once a month on an average, the hind shoes giving out first, partly because of the greater strain on the rear hoofs and partly by reason of the sudden jerks, which have the constant tendency to throw off the shoe. The danger from a loose shoe is that it may throw or cut the horse, and so, perhaps, fatally injure it. A shoe made of inferior stock is apt to break in the center, with serious consequences to both horse and driver; hence owners of good animals are particular in having the best hand made shoes. A good shoe can be forged over when the horse outgrows it, which is also to the advantage of the smith.

Everybody, we suppose, has seen a horse shoe forged. Everybody remembers the time when, a little boy, he stood at the smithy door and listened to the wheezing of the anvil below. Presently the brawny armed workman plucked a piece of glowing iron from the fierce fire and began pounding it with his hammer and cringing it over the pointed end of the anvil. Again he heated and again he pounded—maliciously as you thought, causing the hissing sparks to fly in your face. Presently you beheld a horse shoe forming under his sturdy strokes. It was a slow, laborious and tedious process. Now you may witness horse shoeing out of a sheet of iron like doughnuts; or you may see another infernal machine chew up a red hot bar of iron and spit out horse shoes by the ton, all shaped, hammered, creased and punched precisely as if done by hand, and equally as good in all respects.

Contraction of the Earth.

An eminent French geologist has been attempting to calculate, on the basis of certain allowable suppositions, the amount, in volume, of the solid shell of our earth which must be crushed annually, in order to allow the shell to follow down after the more rapidly contracting nucleus. He shows that the amount of crushed and extruded rock necessary for the supply of heat for the support of existing volcanic action can be supplied by that extruded from a shell between 600 and 800 miles thick, and that the volume of material, heated or molten, annually blown out from all existing volcanic cones could be supplied by the extruded matter from a shell of 200 to 400 miles in thickness. On data which seems tolerably reliable, this investigator has further been able to calculate, as he believes for the first time, the amount of annual contraction of our globe, and to show that, if that be assumed constant for the last 5,000 years, it would amount to a little more than a reduction of three and one-half inches on the earth's mean radius.

At the rate of contraction of three and one-half inches in 5,000 years, as above noted, it would require 90,000,000 of years to diminish the earth's radius by one mile; and, therefore, if there be any correctness in these data, the resulting figure expressing the age of the earth will be large enough to satisfy all the demands of the most extreme geological theories.

A CAR LOAD.—It is now a matter of interest to many people to know what constitutes a car load. Nominally, a broad gauge car load is 20,000 pounds, dead weight, as follows: 70 barrels lime, 70 barrels salt, 90 barrels flour, 60 barrels whiskey, 200 sacks flour, 340 bushels wheat, 300 bushels corn, 680 bushels oats, 400 bushels barley, 360 bushels flaxseed, 360 bushels apples, 430 bushels Irish potatoes, 360 bushels sweet potatoes, 1,000 bushels bran, 6 cords soft wood, 4 cords hard wood, 18 to 20 head cattle, 50 to 60 hogs, 80 to 100 sheep, 9,000 feet solid boards, 17,000 feet siding, 15,000 feet flooring, 40,000 shingles, 20,000 do. hard timber, 10,000 do. green timber, 40,000 feet joist, scantling and all other large timbers.

The Gatling Gun Improved.

The *Hartford Times* says: Dr. R. J. Gatling, the inventor of the well known gun, is one of those peace men who believe that it is better to attempt to make war unprofitable by appealing to fear than to make peace possible by appealing to love. If two contending armies are certain to be annihilated in the first general battle, there will be few battles. At least this seems to be the theory of his machine gun; it has immensely increased man's power for the disabling and destruction of his enemy. The Gatling gun is a group of rifle barrels arranged around a central spindle or axis, revolved by simple mechanism, and loaded and fired by equally simple devices. It differs from the revolving pistols in the fact the revolvers fire only when the barrel and the loading mechanism are at rest, while the Gatling gun fires only when the entire mechanism is in active operation. At all times during the working of the gun, each cartridge that has entered the loading cylinder, at the rear of the barrels, is in process of being placed in one of the barrels and fired, or its empty shell is being withdrawn. The result is a firing so rapid that its noise is continuous, and the ear is quite unable to distinguish the successive discharges. Heretofore each gun has had ten barrels; but recent improvements have made it possible to secure as good results from five barrels as formerly from ten. This has greatly reduced the weight of the piece, diminished the chances of a disarrangement of any of the parts, and increased the gun's effectiveness by making it more portable. This is the most striking change noted by the ordinary observer in comparing this new model and the former style.

But some other changes have been made that are fully as important, though not so easily made plain to the general reader by description. The rapidity of working the gun has been increased by attaching the operating crank directly to the revolving shaft, instead of employing the medium of worm and wormgear. The cartridges are fed directly over the center, insuring their passage to the interior of the barrel without possibility of failure. The mechanism to produce the sweeping motion intended for operating over a radius of a horizontal circle, has been simplified by substituting a cam for the double screw. This cam moves the pieces through four degrees, and a simple adjusting screw increases this 15 degrees, so that the sweep of the gun may be made to describe an arc of 20 degrees without moving the carriage, tripped or swivel upon which the gun is mounted. The frame of the new gun is a single bar passing longitudinally under the gun, instead of two side bars. Some will be made, the support of which will be a case surrounding the barrels and furnished with trunnions on the outside. This will give the smaller size of gun very much the appearance of a howitzer, as the case will be made of bronze. In fact, the new model gun has a case to cover the barrels as a protection from rust, dirt and casual injury.

By these and other minor changes one of the smaller sized guns is reduced in weight from 135 to 98 pounds. On the larger sizes the reduction may not be so large proportionately, but it is sufficient to make a favorable item. The efficiency of the gun is increased—a late trial giving 1,000 shots per minute with a five barreled gun. Any one of the locks can be withdrawn instantly in case of injury, and still the gun may be fired, losing only so much of its efficiency as the proportion of the removed lock is to the remainder. This gun is made of varying calibers, including all the rifle calibers used by civilized nations, and heavier calibers up to the half-pound shot of one inch diameter with an effective range of two and a half miles.

Tea—Its Culture in California.

A writer in the *Chronicle*, who has traveled extensively, says: The tea plant grows better in California than in China, but to the aqueous infusion it yields no thiene, which is the esteemed element. The tea plant grows well in California. We have seen a million of them, in full and luxuriant growth, among the foothills between Georgetown and Placerville. We tasted the infusion from its leaves, served Japan fashion, which differs materially from Chinese methods. Instead of iron plates, heat is applied to the leaf from Japan, through a porous paper, expressly made, so that there is no burning nor overheating. We have taken tea which came from Assam and also from the vast tea gardens of the snowy Himalayas; and between teas of China and Japan there is a marked difference. The teas of India are too rank; they are only used to give pronounced flavor to the teas of China, which are growing year by year more insipid. We are not surprised to find in this first tea of California quite a difference from all others. It was not rank but delicate; and considering that it was rudely prepared and fired through Japan tea paper in haste for our industrial fair, we judged that tea culture may be a success in California when it can be economically aided by machine preparation. The tea plants of El Dorado were all destroyed by a casualty that is avoidable in the future. The experiment otherwise proved that with irrigation tea will grow first rate in our foothills, and all the better where snow covers the brush for 60 days.

There are now 25 men engaged in graveling and leveling the railroad track between Walla Walla and Wallula.

SCIENTIFIC PROGRESS.

The Temple of Belus—Some Interesting Discoveries.

Mr. George Smith states, in the *London Athenaeum*, that he has recently discovered, in his researches amid the ruins of Nineveh, an ancient tablet which gives a remarkable account of the temple of Belus (the ancient tower of Babylon), in which are given the principal points of arrangement and dimension of this remarkable structure.

This temple was the grandest religious edifice of the age—the center of religious worship and the wonder of the world. It was founded centuries before Babylon became the chief city and capital of the State, and retained its fame even down to the commencement of the Roman empire.

Our knowledge of this structure has heretofore been confined to what Herodotus and Strabo have told us of it. They tell us that the principal building was one story in length and breadth and high, and that it consisted of eight stories or towers, one above another, the whole forming a pyramidal shape—the highest being the chief sanctuary or holy of holies of the Babylonian worship. A stade has been supposed to be 600 feet, which would give the dimensions of the structure as 600 feet square and 600 feet in height.

But the tablet which Mr. Smith has brought to light, and which undoubtedly gives the correct measurement, changes those figures very considerably.

First, in the tablet we have the measure of the inner enclosure, called the "Grand Court," which is given at 1,156 feet in length and 900 feet in breadth. The next court is called the "Court of Istar or Zamma," which is set down at 1,056 feet in length and 450 feet in breadth. Round this court were six gates, admitting to the inclosed temples. Even the names of these gates are given. The four walls of the courts, like the great pyramid in Egypt, faced the four cardinal points, and in this the faces or sides of all the other portions of the structure agreed. The extent of the next enclosure appears to be uncertain; it had four gates or entrances—the gate of the rising sun, the southern gate, the gate of the setting sun, and the northern gate. Each of these three enclosures seem to have been on a level with the general plain on which Babylon stood, and were simply walled paved courts, open at the top, and one within the other.

In the center of the third enclosure stood the "tower" or principal building, which was the grandest portion of the whole pile, the foundation of which was 300 feet square, and the entire height, above the foundation, also 300 feet. The lower stage or story was 300 feet square and 110 feet high. The next or second stage of the tower was 260 feet square and 60 feet high. The epithet applied to this stage is obscure; it had probably sloping sides. The third stage differs widely from the lower ones, and commences a regular progressive series of stages, all of equal height. It was 200 feet square and 20 feet high. The fourth stage was 170 feet square and 20 feet high. The fifth stage was 140 feet square and 20 feet high.

Probably by accident, the dimensions of the sixth stage of the tower are omitted in the inscription, but they can be easily restored in accordance with the others. This stage must have been 110 feet square and 20 feet high. On this was raised the seventh stage, which was the upper temple or sanctuary of the god Bel.

This building had a length of 80 feet, by 70 feet broad and 50 feet high.

Thus the whole height of this tower above its foundation was 300 feet, exactly equal to the breadth of the base; and, as the foundation was most probably raised above the level of the ground, it would give a height of over 300 feet above the plain for this grandest of Babylonian temples.

This grand central tower or temple was surrounded with a number of smaller buildings, the chief of which, and the one which appears to have been most intimately connected with the principal structure, was 200 feet square. Beyond this, and around the base of the tower, were arranged the chapels or temples of the principal gods, on its four sides, and facing the cardinal points. On the eastern side stood a sanctuary or temple, 117 or 133 feet by 67 feet, with 16 shrines, the principal being the shrine devoted to the god Nemo and Urmit or Trasmir his wife. Nemo was considered the eldest son of Bel, the great deity of the temple. On the northern side stood two temples, one devoted to the god Hea, the other to Nusku. The temple of Hea was 142 feet long by 50 feet broad, and that of Nusku was a square, 58 by 58 feet. On the southern side stood a single temple, dedicated to the two great gods, Ann and Bel. This was 117 by 50 feet. On the western side were the principal buildings, consisting of a double house, with a court between the two wings. On the one side the wing was 166 by 34 feet, on the other side the wing was 166 by 108 feet, and the space between them was 58 feet. The building at the back was 208 by 50 feet. The description of the position of the western temples must be taken as conjectural. In

these western chambers stood the couch of the god, and the throne of gold mentioned by Herodotus, besides other furniture of great value. The couch is stated to have been 15 feet by 6 feet 8 inches in area.

The mound of Babil, which is already identified by the best authorities with the temple of Belus, consists now of the lower stage of the tower and the ruins of the buildings around it. We can only conjecture that the magnificent superstructure was removed by Alexander in his operations for clearing the site and rebuilding the temple, a work he did not live to accomplish.

The adornment of the temple of Belus with gold and silver, the splendid colors of its furniture and statuary, combined to make it one of the grandest buildings of the ancient world, and earned for it the name of the "Basis of Heaven and Earth," and the "Glory of the City of Babylon."

The discovery of these and other tablets—constituting the books and libraries of that ancient people—are among the most interesting scientific discoveries of the age. Their number seems almost without limit, and the information which they are bringing down to us from those far off ages is of the most important character. The constantly recurring reports of new discoveries in this direction, keep up the interest, and will tend to secure, beyond peradventure, the funds necessary to continue the work of exploration, so long as the discoveries continue. This field of research seems almost inexhaustible.

AN INTERESTING EXPERIMENT.—There are some substances—arsenic, for example—which under ordinary atmospheric pressure pass from the solid to the gaseous state without first fusing; whereas, with increased pressure, they can be fused. A good lecture experiment for showing that the phenomenon depends on pressure has been described by M. Meyer, to the Berlin chemical society. Into two similar tubes, with one end open, are introduced a few grammes of iodine. The upper open ends are drawn out, the air is removed from one of the tubes, while that in the other is gently heated; then both are closed by fusing. The iodine in the two tubes is now heated with a Bunsen burner. In the air-containing tube the iodine fuses, while a colored almost opaque vapor is given off, and on turning up the tube the fused iodine runs down and solidifies again on the cold sides. In the vacuum tube, on the other hand, the iodine does not fuse, but is at once vaporized, and a vapor cushion is formed between the crystals and the glass, as in Leidenfrost's phenomenon. The vapor is but little colored and quite transparent; because, air being absent, it rises at once to the cold parts of the tube and forms a ring of sublimated iodine.—*Boston Jour. of Chemistry.*

OCEAN CURRENTS.—Prof. Wyville Thomson, director of the civilian scientific station still on board the *Challenger*, reports to the admiralty that the trough of the Pacific ocean, like that of the Atlantic, is by an enormous mass of cold water near the bottom, which appears to be an indraft from the Antarctic ocean, constantly moving northward. We know that the same thing takes place in the Atlantic, where a cold under-current moves from the Arctic regions to the equator, while on the surface a warm current (the gulf stream) moves in the opposite direction from the equator to the pole. The cause is nothing but the difference in specific gravity; in cold regions the water of 39 deg. Fahr., being most dense, will sink and make place for the warmer water, which will overflow it on top, coming from the warm regions, where the cold water will ascend and be heated by the solar rays, and flow toward the poles. This motion is governed by the same law as air, heated at one place and cooled at the other; at the cold place the air will descend, flow over the bottom to the warm place, ascend there, being heated, and flow from the heated place on top in a contrary current over the cold air, thus establishing a constant circulation.

THE ELECTRIC LIGHT IN PARIS.—We learn from recent foreign journals that the luggage room of the Paris terminus of the Great Northern railway has been lighted by means of electricity for some days, and so successful has the experiment proved that it has been decided to light all the waiting and baggage rooms of the principal Paris railway stations by means of electricity. By working the Gramme machine with three-horse power, as much light is obtained as that given by a hundred gas burners. The electric lantern is placed at a height of 10 meters (about 32 feet) from the ground, and sheds a soft, clear light over an area of 20,000 square feet.

In reference to the amount of carbonic acid excreted in the breath and perspiration by different animal species under the same conditions, and by the same species under different conditions, Dr. Pott finds that the greatest amount of carbonic acid per 100 grms. of living weight is excreted by birds (4.93 grms. in six hours); next follow mammals (2.95 grms. in six hours), and then insects. Young animals excrete a proportionately greater weight than old ones.—*Chem. News.*

INTERNAL CONSTITUTION OF MAGNETS.—In the *Comptes Rendus*, for January 3d, 1876, M. J. Jamin shows that a bundle of steel plates will always be stronger than a single bar of steel of the same dimensions, and the proportion will increase indefinitely with the number of the plates. This view justifies the use of slender laminæ in the construction of magnets.

MECHANICAL PROGRESS.

Our Iron Industry.

A large share of attention is of late being drawn to the iron industry of the South, through a district of country embracing the southern portion of West Virginia and thence south to the northern portion of Georgia and Alabama. In addition to a superabundance of the ordinary iron ores of the very best quality, many veins of manganese are also found there; also black oxide of great purity, brown hematite and magnetic ores. "Brown ochreous ore" occurs, with from 53.20 to 58.80 per cent. of metallic iron.

Many of the ores found there are of the very best character for the production of Bessemer steel, and many, not strictly Bessemer ores, have gained high favor as furnace ores for foundry and mill irons, both from the fluidity and from the unusual strength of the resulting metal. In 1874 a series of most satisfactory tests of various pig irons from these ores was made at Providence, R. I., with the Government machine for testing gun metal. The irons were of anthracite make, and among them was found, so far as known to the experimenters, the strongest anthracite iron on record. The iron from most of these ores is remarkably free from sulphur.

Who shall estimate the importance of this iron producing region in the near future? It is located in a fertile agricultural region, convenient to an abundance of the best coal, and in convenient railroad connection with all parts of the Union. Foreign capital is fast becoming interested in these properties, and the prophecy is ventured that the products of this region will soon secure the control of the iron market of the Atlantic coast, and eventually be able to compete successfully with British iron and steel in the English markets.

The iron region of West Virginia is within 100 miles of tide water and ocean navigation at Richmond, where navigation is never closed, even in the coldest season.

The Iron Works of the United States.

No greater evidence of the sure and rapid progress of the iron interest of the United States can be given, than is contained in a small "Centennial" publication of 140 closely printed pages, recently put forth by the American iron and steel association. A summary of the prominent facts more fully treated upon in the book is given below:

Whole number of completed blast furnaces, Jan. 1st, 1875.....	713
Annual capacity of all the furnaces, in net tons.....	5,439,230
Whole number of rolling mills, Jan. 1st, 1875.....	332
Whole number of single puddling furnaces, (each double furnace counting as two single ones).....	4,474
Total annual capacity of all rolling mills in finished iron, net tons.....	4,189,760
Annual capacity of all the rail mills in heavy rails, net tons.....	1,940,300
Number of Bessemer steel works, Jan. 1st, 1875.....	11
Annual capacity in ingots, net tons.....	500,000
Number of Bessemer converters.....	24
Number of open-hearth steel works, Jan. 1st, 1875.....	16
Number of open-hearth furnaces.....	22
Annual capacity in ingots, net tons.....	45,000
Number of crucible and other steel works, Jan. 1st, 1875.....	30
Annual capacity of merchantable steel, net tons.....	108,250
Of which there are of crucible steel, in net tons.....	45,000
Number of Catalan forges, making blooms direct from the ore, Jan. 1st, 1875.....	39
Annual capacity in blooms and billets, net tons.....	59,450
Number of bloomeries, Jan. 1st, 1875, making blooms or pig iron.....	49
Annual capacity in blooms, net tons.....	60,200

New Cask Making Machinery.

An invention, the result of which may hereafter have a very serious effect on the skilled labor market in certain departments of trade, was recently exhibited at the works of Messrs. Ransome & Co., sawmill engineers, King's road, Chelsea, Eng. The invention referred to is a series of improved machines, about a score in number, constructed for making casks for beer and hogsheds for wine. The great merits of Messrs. Ransome's patent are not only an improvement upon former patents which they have pressed into their service, but the combination of their own inventions with those of previous date, and the formation of the whole into one general system.

Practical illustration was given that casks for holding liquids of all kinds can be produced entirely without the aid of the skilled cooper at less than half the cost for labor, and when it is stated that one machine alone, worked by a lad, will joint in the most perfect manner six staves in a minute, while another will turn, bevel and oval a head with mathematical accuracy in less than that space of time, the great economy is at once apparent. Apart from the utility of the invention, or combination of inventions, it is a true artistic treat to witness the working of this massive clockwork machinery, and visitors were loud in their admiration of a most interesting and, indeed, educating exhibition.—*Iron.*

The Length of Rails.

We have made several allusions to the feat of the Edgar Thomson steel company in making rails of the previously unheard-of length of 60 feet. That new company signalized the starting of its works by the accomplishment of this extraordinary production. The feat was a matter of no little interest to iron masters and railroad men generally, and seems to have been accepted by our English cousins as a challenge of ability to produce long rails. And now we are informed that a manufacturer in England has produced a rail over 100 feet in length; nearly doubling the boasted feat of the Edgar Thomson company. No doubt we shall soon hear that the American company has produced rails over 100 feet in length, as Americans never like to be outdone in such matters, especially where they take the initiative.

But what is the use of such rails? Are they of any superior economic value to the common 30 foot rail? It is now very generally affirmed that the longer the rail the better, because there is less loss in cropping the ends to make a square joint, less expense in handling (within a reasonable length), and what is still more important, long rails require less joints to the mile of track, and thereby save the pounding and hammering so wearing to rolling stock and so unpleasant to the passenger. Nearly all writers upon the subject seem to agree that long rails are conducive to both economy and safety. Indeed, we have noticed but a single exception, and that in case, an intelligent correspondent of the *American Manufacturer*, who advances some most potent reasons for adhering to the 30 foot rail, which we will briefly refer to and condense under the following head:

How do Rails Become Dangerous?

In the manufacture of rails from the ingot by passing the iron between the rolls, the flange is drawn much thinner than the head, so that when the rail has left the rolls the flange cools so much more rapidly than the head that the rail, by the time it becomes cold, is curved into the form of a segment of a circle, with the flange on the outside. To obviate this difficulty it is usual to bend the rail as it drops from the rolls into the opposite direction, so that when it cools it will become straight. Manifestly this can be only imperfectly accomplished, especially with a very long rail, and hence the final work must be done by "cold straightening."

Now the physical construction of iron is not absolutely solid. It is, in fact, composed of particles which adhere by cohesion, induced by impact. The particles are thus imperfectly joined at best. Their cohesion, moreover, it is well understood, is less in proportion as the temperature of the iron is increased, hence hot iron may be easily bent, while cold iron is very rigid, and hence, furthermore, any disturbance of the particles of iron when cold, works a greater injury to their adhesive power or strength than the same degree of disturbance when hot.

For this reason cold straightening is more injurious to a rail than straightening when hot; therefore that method should never be resorted to when it can be avoided. Moreover, injury to rails by cold straightening cannot be detected by the usual inspection or tests, but the defects which inevitably follow such a process must exist to the detriment of the rail, and, in an unknown degree, to the danger of the passenger. It is well known that "broken rails" usually occur from damage originally caused by cold straightening. Hence, the proper length of a rail is the limit at which a rail can be drawn without the need of any serious straightening after it becomes cold. That limit, it is said, is 30 feet; while 100, or even 60 feet, unavoidably produce curves which require such a large amount of cold straightening as to render the rail very unsafe for use. The writer concludes his article as follows:

"I claim that 60 or 100 foot rails cannot be hot straightened perfectly. Secondly, that cold straightening is injurious to the physical structure of the metal. Third, that a higher per cent. of perfect rails can be made at 30 than 60 or 100 feet. Fourth, that 30 foot rails can be handled, shipped and put into position at less cost than 60 or 100 foot rails. Fifth, that the rail joints can be made as serviceable and as safe as any other part of the track. Consequently the innovation proposed of 60 or 100 foot rails will add to the expense of the rails, and at the same time surely tend to increase their defects without a single redeeming compensation."

"WHAT IS STEEL?" seems to be an unanswerable conundrum just now among metallurgists. Sir Joseph Whitworth proposes the following: "With so many rival and unsatisfactory definitions of steel, the writer would do away with all the different names by which various kinds of steel are known, such as blister, shear, double shear, common steel, spindle steel, silver steel, cast steel, etc., which carry no precise definite meaning; and would express what is wanted to be known by two numbers which should represent tensile strength and ductility."

POMPEO ENGINE FOR THE WATER WORKS AT HULL, ENGLAND.—A new Cornish pumping engine was started at the above named place on the 28th of December, 1875. This engine is one of the largest of the kind yet constructed, having a 90-inch cylinder, with a stroke of 11 feet, and presents, especially in the pumping arrangements, several peculiarities. The *Engineer* (London) promises illustrations of the machine at an early impression, merely making the chronicle of the start with the statement that it was in every respect successful.

JOSEPH CUNRO, while engaged in wheeling a barrow full of refuse rock, at Volcano, last week, found in the lot a large piece of quartz which was full of pieces of gold, making the whole specimen worth from \$500 to \$1,000 in gold.

THE rainfall at Shasta this season amounts to 85.02 inches. Shasta is about the wettest place in the State, the amount registered in one year being over 90 inches.

ALL the mills on the Carson river are running to their full capacity, with plenty of water and plenty of ore on hand.

DAYTON.—Gold Hill News, March 23: Sluicing the main shaft is making rapid progress, the bottom in good working ground. The station set for the 700-ft level has just been completed. The north and south drifts on the 600-ft level are each pressed steadily ahead, running parallel with the ore vein. These drifts are

gradually laying bare a large portion of the ledge ready for cross-cutting, and it is reasonable to expect some lively ore developments on that level soon. The north drift a day or two since tapped a considerable stream of water, but which has not yet given any trouble whatever.

BULLION.—Sinking the main incline has been resumed and is making excellent headway. The north drift on the 1400-ft level has been cleaned out and repaired for a distance of 256 feet. The up-ramp from the 1700-ft level is steadily advancing, the face in fine working ground. The northeast drift on the 200-ft level of the Imperial shaft is being pushed ahead with all possible energy toward the ore vein, the face still in hard blasting rock. It will probably take 10 days or two weeks yet to reach the black dikes and heavy clay always found on that portion of the Comstock lying next to the ore vein.

SIERRA NEVADA.—Sinking the shaft below the 1500-ft level is making excellent progress. The main south drift, on the 1000-ft level, is steadily pushed ahead to connect with the winze now being sunk in the north drift on the 700-ft level of the old shaft.

VERMONT.—Sinking the shaft is going forward at a fair rate of speed. The main incline is being drilled out well, and the work being pushed with all possible energy. The superintendent, Mr. J. P. Hutchinson, has just returned from San Francisco, where he has contracted for steam hoisting machinery of a power sufficient to sink the shaft and prospect the mine to a depth of 1,200 feet or more. Preparations for the erection of this machinery, as soon as it arrives on the ground, are now being made, and it is expected that the mine will take but a very short time to have it set up and in good running order.

MEXICAN.—The course of the north drift, on the 1465-ft level, has been changed until the drift is skirting the east clay selvage of the ore vein, cutting occasional spools and streaks of ore. The drift will be continued in this way for some distance, and the ledge will be exposed in a more favorable position than the ore body determined. The ore where it was cross-cut farther back shows great richness, and taken altogether, is of a good milling character. The average assays are excellent, and there is not a doubt but a fine paying ore deposit is being opened.

CROWN POINT.—Daily yield, 350 tons of ore—keeping the mills steadily running. On the 1600-ft level a cross-cut has been run near the foot of the south winze No. 2, penetrating the ledge for some distance, showing the ledge to be solid quartz and low grade ore. The main south drift, on the 1600-ft level, is steadily advancing toward the Belcher line. The east drift on the 1700-ft level has reached the wall of the ledge, finding only quartz and low grade ore in its course. A drift south has been started on this ore vein, which has not yet made any important developments.

IMPERIAL-EMPIRE.—The north drift on the 200-ft level is steadily advancing toward the Alpha ground, the face still in rich ore. The steady development of this body of ore is not only placing the Imperial once more in a fair way to join the ranks of our dividend paying mines, but is also leading to the almost inevitable conclusion that the Alpha will yet prove itself to contain a bonanza hardly second to that of the Consolidated Virginia mine.

CONSOLIDATED VIRGINIA.—Daily yield, 750 tons of ore, keeping the mills all crushing up to their full working capacity. The yield of bullion for the month of March is already upwards of \$2,000,000, and exceeds that of February by about \$400,000, at the same date. Providing all that no unavoidable circumstances happen to prevent, the production of the mine will for the month exceed \$3,000,000. These facts need no comment; they speak for themselves in language so forcible that to attempt to add a word would be folly. One wrong impression in regard to the mine that seems to have gained some credence, we desire to set right, and that is that this mine is being rapidly exhausted of its rich ores. Those who argue thus, forget three most important facts, the first of which is, that the mine is not yet in length, and on the 1500-ft level is almost all rich ore that needs no assorting, and contains no horse or patch of waste to amount to any consideration whatever. The second is, that instead of the ordinary, small and narrow stripe of ledge and streaks of ore usually found, this ore vein on the same level ranges from 250 to 300 feet in width, and that when a breast of that immense width is cut out, the waste will be so small, and the waste, or even poor ore to separate, the extraction of 750 tons of ore per day makes a most insignificant showing. The third is the fact that the mine has been prospected by means of winzes to a depth of 147 feet below the 1500-ft level, sufficiently to know that the ore not only extends downward to that depth, but that its quality is as rich and is almost, if not quite, as good as that of the first 147 feet. The ore is worked on the 1500-ft level. These facts insure as large a body of rich ore to extract from below the 1500-ft level, as there has been above, and taking into consideration the immense amount of rich ore yet above that point, it is literally impossible for the best mining experts to set a time for the exhaustion of the mine, laying aside all conjecture whatever in regard to what may be found in the depths below the 1500-ft and 1700-ft levels, and that none can tell until the miner's pick has solved the problem.

CALIFORNIA.—Sinking the O. & C. shaft has been impeded somewhat during the past few days by an unusual heavy flow of water. Day before yesterday the flow had increased to 24 inches, miners' measurement, which, although handled easily by the pump, was too strong to allow men to work at the bottom. Yesterday the water was again gradually on the decrease, and the men resumed work at the bottom on last evening. The winze being sunk in the cross-cut No. 6, on the 1500-ft level, has reached and connected with the north drift on the 1500-ft level, and is now being continued on downward to reach a point at which it is desired to connect with the Ophir mine on the 1465-ft level, for air purposes. The north drift on the 1400-ft level is being steadily pressed ahead, also to connect with the Ophir at that level. The California mill, with a crushing capacity of 300 tons per day, will be started on the ore from this mine on the first of the coming month. This will, of course, lessen to some extent the yield of the Consolidated Virginia for the month of April, but will add an increase, if anything, to the combined bullion production of the two mines.

HEXORLE.—Daily yield, 450 tons of ore. The ore breasts are both looking and yielding well, the ore continuing of a fine character, rich in gold. The mills are kept steadily running, and the bullion yield of the mine will not fall short of that of last month. The dumps are kept well supplied with ore, which is being shipped to the mills as fast as it is extracted. Sinking the air shaft below the 1500-ft level is going steadily ahead. The prospecting winze below the 1500-ft level are looking finely and promise a development of a body of good paying ore in that portion of the mine. The north drift on the same level is also showing well. The excavation for the new pumping machinery on the surface at the air shaft is going steadily forward. The erection of the new tar-house and vat to be heated by steam for tarring the hoisting cables is nearly completed.

GRIMM.—Daily yield, 150 tons of ore. The ore breasts on the 1500 and 1465-ft levels are looking splendid, and continue their regular supply of good milling ore. The drifts on the 1600-ft level have been cleaned out and repaired into the face of the ore breasts on that level, so that the extraction of ore at that point can be resumed whenever it is desirable or necessary to do so. The east shaft connecting with the 1700-ft level has been cleaned out and repaired to within a very short distance of the bottom. A drift south on the ore vein has been started on the 1100-ft level. The prospects at that point are quite favorable. The enlargement of the shaft is rapidly approaching completion. The mills are kept steadily crushing ore from the mine. The new office and assay rooms are rapidly approaching completion. The machinery is all working splendidly, and

the future again begins to look more hopeful and prosperous.

LADY BRYAN.—Sinking the shaft is making steady progress, the bottom in good sinking ground. South cross-cut No. 2, on the 330-ft level, is being pushed steadily ahead, the face in softer ground, with evident indications of a more favorable ledge formation ahead. The ore prospects on this level are growing more favorable as the work of development proceeds. The main south drift on this level is steadily advancing to the southward, without change of interest to note. The mill is running steadily on ore from the mine.

JULIA.—Sinking the shaft below the 1700-ft level is going ahead at a very rapid rate, the Burleigh drills in the bottom doing excellent work. The bottom is still in quartz, clay and porphyry, mixed. The character of the ground evidently indicates a near approach to the main ledge. There is no water whatever. The face of the main southwest drift on the 1600-ft level is still in quartz of a very encouraging character. The ledge on this level is showing much more concentrated than it was on the 1400-ft level, and the indications are still growing more favorable for the development of a paying mine at no very distant day.

GOULD AND CURRY.—No developments are being made on any of the lower levels, the entire work in the mine being confined to repairing the shaft, and the main north drift connecting with the Best & Belcher on the 1700-ft level.

ROBERT.—The mine is looking well at all points. The face of the south drift on the 350-ft level is showing some very rich ore, the drift advances to the southward. The north and south drifts on the 500-ft level are each steadily advancing, running parallel with the ledge, and cutting occasional streaks of fine quartz and ore of a very encouraging character.

BALTIMORE AND AMERICAN FLAT.—It is the intention to crowd the shaft downward to the 1250-ft level, at which point a new ledge will be immediately opened. The prospecting drift on the 1050-ft level is steadily pushed ahead, the face in very favorable ledge material. The face of this drift has been drawing a strong flow of water for several days past.

YELLOW JACKET.—A new and important ore development was made yesterday in the middle cross-cut on the 1940-ft level. Just the extent of this discovery, of course, cannot yet be determined; but so far as development looks very much as if the Yellow Jacket was on the point of again coming to the front ranks with another rich ore body.

UTAH.—The repairs to the drifts and air winzes on the 400-ft level are nearly completed. The lining of this portion of the work again gives an excellent ventilation of the entire mine from the 400-ft level to the surface.

KNICKERBOCKER.—Some time since all work was stopped on the lower levels by a heavy flow of water from the face of the drift. This water has again been drained, and work will be commenced on both the 600 and 700-ft levels in a very short time.

AMAZON AND GLASGOW.—The new hoisting machinery was started into full operation on last Monday, the whole working with the utmost perfection. The water is now nearly drained from the shaft ready to resume sinking and cross-cutting the ore vein on the third station level.

ALTA.—The main shaft is now down 1,045 feet. The flow of water is slight; excellent progress is being made.

NORTH CARSON.—The ore developments on the 300-ft level are showing more favorable every day. On the east side of the ledge the rich vein of ore found on the level above has widened to four feet, the whole being of a rich milling quality.

NIAGARA.—The new works are completed, and sinking the main incline shaft has been resumed under the most favorable auspices.

GLORY CORN.—The north drift on the 300-ft level is steadily advancing, the face showing some very favorable streaks of ore. A drift south has been started in the ore vein on the same level, which is also looking quite encouraging.

PICOT.—Some little increase of water is met with in the north drift, and better assays have been obtained from the quartz seams in the face of the drift during the week.

SILVER CITY.—The ore stopes in the raise from the bottom of the shaft are yielding rich ore.

BUCKEYE.—The shaft has been drained and work resumed on the lower levels. Ore of a good milling quality is being extracted.

LADY WASHINGTON.—Sinking the shaft is making excellent headway, the bottom in soft ledge material. The indications grow more favorable every day.

LEO.—The face of the south drift from the bottom of the winze is still in fine ore, and the amount of ore has already been extracted ready for milling.

HALE & NOBLES.—Excavating and putting in the stone foundations for the coming new and powerful pumping machinery is being pressed toward completion with all possible haste.

CALEDONIA.—The flow of water is still great, but is easily handled by the pumps.

HEBRON.—The new machinery is now received and on the ground, and is being put in position as fast as possible.

CHOLLAR-POTOSI.—No ore is being extracted on account of the condition of the roads. The erection of the powerful hoisting engine is going forward as fast as the nature of the work will admit.

NORTH CONSOLIDATED VIRGINIA.—Sinking the shaft is making the usual good progress, the bottom in good working ground, carrying streaks of quartz of a very favorable character. It is now down 675 feet. The flow of water shows slight increase.

SAVAGE.—The pumps and bailing tanks still hold the water at the 1800-ft level. Nothing is being done in the mine whatever except cutting out for the pump stations for the new pumps.

OVERMAN.—Owing to a disarrangement of some of the machinery, nothing has been done in the shaft during the past week.

SULLIVAN.—The foundations for the new machinery are completed, and the cross-cut has been penetrated the ledge for a distance of 250 feet, the face still in quartz and low grade ore.

SILVER HILL.—Sinking the main incline has been stopped on account of the strong flow of water, which made it necessary to put a plunge pump to work at the head of the incline.

NORTH DAYTON.—The quartz in the face of the north drift is very rich, but gives excellent average assays to both gold and silver.

BEST AND BELCHER.—There is nothing doing in the mine, except the prosecution of the repairs to the main drift connecting with the Gould & Curry on the 1700-ft level.

TRJAN.—The erection of the new hoisting works is progressing rapidly.

DARDANELLES.—The face of the north drift, on the 1400-ft level, is looking much more favorable.

OSCEOLA.—The face of the main north drift still continues in good paying ore.

ALTA.—The shaft is drained of the flow of water recently struck and the sinking has been resumed.

NEVADA.—Continued improvement is met with in the face of the main north drift, more quartz coming in which gives better assays.

SUPERIOR.—Shaft 58 feet deep. No water to interfere.

ORIGINAL GOLD HILL.—South ore body continues looking well.

(Continued on Page 220.)

PAGE has presented in Congress resolutions of the California Legislature, asking further appropriations for Oakland harbor, and that a lighthouse and oak be placed in Carquinez straits.

Mines and Mining Down the Creek.

Time was when the major part of the gold sent from the Grass Valley mines came from below Boston ravine. Then Rocky Bar, Massachusetts Hill, New York Hill, North Star, Lone Jack, Allison Ranch, and others, produced their millions annually, and sometimes monthly, and all the hills and slopes were dotted with the cottages of busy and prosperous miners. Then from one cause and another, but in no case because the lead was worked out, these mines were "hung up" and the prosperity of Grass Valley depended mainly upon the Eureka, Idaho, Empire and other mines up the creek and across from town, and many a deserted cabin and cottage betokened the change down the creek; but a large number of families have remained in their little homes, the heads thereof while away over the mountains earning wages being confident that the day would come when their services would be needed here again. The time is evidently near at hand. A little over a year ago, when the North Star shut down, the only mining work going on in all that region below town was on the New York Hill and Omaha, then just exploring with a few men. Now each of these mines is working hundreds of men, and gold bullion in good quantity is regularly turned out; the Franklin Allison Ranch, an extension of the famous old mine, is about putting on pumping and hoisting machinery to take out the quartz already proved to be paying in quantity and quality; the Homeward Bound, which lies between the Franklin and the Lone Jack and Omaha, has extensive machinery purchased, to be put on and in motion as soon as the roads permit of hauling; this mine has been prospected near the surface its entire length and the pay chute proved to be continuous, so there is no doubt in the minds of miners who have worked there of its capacity for making a paying mine; the Prospect is only waiting the decision of its managers as to the kind of reduction works to be put up to step into line as a bullion producer; big Fryer works are to be put up on Perrin's mine near Forest spring; the owners of the Lone Jack, on a home side proposition to purchase, a short time since, asked \$100,000 for the property, so it is not likely, with good prospects and encouragement on all sides it will be allowed to remain idle long; the North Star gives certain premonitory symptoms of resumption—we are not at liberty to say exactly what; Rocky Bar is moving slowly but surely in the direction of starting up that host of Grass Valley mines, and altogether the outlook for lively times down the creek is extremely flattering. A thousand additional men set at work in that direction during the Centennial year would add largely to the business and prosperity of Grass Valley.—*Foothill Tidings.*

SILVER COIN.—Advice from Washington dated March 20th says: The Treasury Department will receive during the present week from San Francisco 14 tons of silver coin. In consideration of the period of commencing the circulation of silver, this will amount to a half million. The amount of silver in the vaults of the treasury at the present time is less than \$30,000. Orders were received at the department to-day for \$120,000 fractional currency, and that amount will be shipped to-morrow to the various points from whence the requisitions were made. There are \$2,000,000 fractional currency still in the vaults, though none has been printed since the middle of last month. Since that time the requisitions upon the treasury from bankers and others, and officers of the treasury to be supplied with fractional currency, have amounted to about \$3,000,000. Several parties have visited the treasury recently with various amounts of silver coin that they had been hoarding, wishing to have it exchanged for notes. The department has in all cases refused to make the exchange, the banks declaring that this class of coin is neither to be redeemable nor exchangeable, and is a legal tender to the extent of five dollars only. The amounts presented have varied from \$5 to \$50.

BULLION CERTIFICATES.—A bill has been introduced into Congress for the purpose of utilizing gold and silver bullion, by permitting it to be received on deposit at the Government depositories, and issuing a certificate to the holder representing its value. An engrossment of this kind was made by the Bulletin several years ago. The operation would certainly be a very convenient one to bullion producers, and would often be a great relief to the money market. It is within the province of a bank or a capitalist to receive bullion, and issue a certificate for its value, redeemable in bullion at the pleasure of the holder. Such a course, however, is surrounded with too many objections to make it popular. Were the Government to sanction the proceeding, public confidence would be enlisted, and the certificates would be received in financial and mercantile circles. From \$7,000,000 to \$8,000,000 might be employed in this way in the payment of duties on imports at this port, in the same manner as 90 per cent. of the duties at New York are paid in gold certificates. The proposition ought to receive the favorable attention of Congress.—*Bulletin.*

The roads are so bad in the vicinity of Fort St. Vrain, Butte county, that ore cannot be taken from the mines to the quartz mill, so mill work is temporarily suspended.

MEASURES are being taken by the Senate Committee on Indian affairs, tending to the cessation of the Black hills to the United States.

The Value of Small Savings.

Few young men have a just appreciation of the importance of small savings at the outset of life. Wealth has quite as powerful a tendency to gather in masses as it has to dissolve into fragments and be scattered. Every little helps; dimes soon become dollars, and dollars can be made to double themselves in due course of time. Most young men, as well as their elders, have small vices, but seldom stop to think what these vices cost in cash, or what might be accomplished with this cash, were it wisely instead of uselessly invested. Suppose a young man is addicted to smoking. He might effect a worse vice, but we will take a mild one for example.

In a week he will consume a quarter of a pound of smoking tobacco (twenty-five cents) and three cigars per day (which is very moderate) at 10 cents apiece, and by the end of the week will have puffed two dollars and thirty-five cents into the air. Three cigars a day at 10 cents apiece make 30 cents, and a 30 cents a day for a week make two dollars and ten cents, which, added to the quarter of a pound of tobacco, make two dollars and thirty-five cents. In a year this would amount to \$122.20. We will suppose the young man to be 21 years of age. Now, instead of smoking this coin away, suppose he should place it in a saving bank at nine per cent. interest, and let it remain there, how much would this little economy alone amount to if he faithfully followed for 10 years? At the end of the first year, as we have said, he would have \$122.20. At the end of the second year the interest on this would bring it up to \$131.97, plus \$122.20 more which he has saved in the same way, making a total at the end of the second year of \$254.17. This, at the end of the third year, by reason of the interest, would amount to \$277.03, and, plus the \$122.20 additional, would make a total of \$399.23 saved in three years. Following the same rule of calculation he would be worth \$557.34 at the end of the fourth year; \$729.67 at the end of the fifth year, \$917.48 at the end of the sixth year, \$1,122.25 at the end of the seventh year, \$1,345.45 at the end of the eighth year, \$1,588.75 at the end of the ninth year, and \$1,853.96 at the end of the tenth year. Should he deposit his savings on this score every three months instead of annually, the gross sum would amount to more than \$1,900. He would be worth that much, at least, at the age of 31, and many a man starts in his career on a less sum.

If he not only avoids smoking, but drinking, billiard-playing, and all other amusements and convivialities that are not at all necessary to his happiness, and saves his money prudently, is there any doubt but that he will be able, at his 31st year, to muster ample capital to safely engage in the business he has been learning thoroughly in the meantime? These calculations are of course based on the supposition that his employment is unbroken. Few young men who secure staple situations never lose them if they attend strictly to their business. Billiard playing costs about three times what smoking does, and there is no limit whatever to the cost of drinking.

If a young man is born to fortune it is advisable that he should devote time to acquiring graceful accomplishments, and it is well enough that he should indulge a taste for lavish wardrobe; but if he is poor and has his way to make in the world, his sole business from the outset should be to prepare himself for making money, and to learn how to make it. He can do nothing without capital, and while he is learning his business he should be gradually acquiring his capital. It is the easiest thing in the world for him to do it if he only pursues the right course, and pursues it systematically. If the government seeks to prepare a future officer of the army it takes a boy 17 or 18 years of age, withdraws him from parental control, excludes him from society, guards him against prevailing vices and frivolities, and requires that he shall devote a series of years to the patient and unremitting study of his profession. When he has mastered its theory, he is usually transplanted to some remote frontier post, there to participate in its actual practice in a subordinate capacity. All our great generals have been trained and disciplined in this manner. The young civilian has severer struggles before him than the military cadet, and has need of more fortitude, self-denial, and eagerness throughout. He should therefore make up his mind at the outset that money is the main, essential object of his worldly pursuits (no matter what may be said to the contrary), and stick tenaciously to a life of policy and conduct that will eventually lead him on to success and comparative fortune.

THE KENTUCKY "FLESH SHOWER."—The telegraph recently announced a shower of flesh which fell in Bath county, Ky. on the 3d inst. The flesh, which covered two acres of ground, resembled mutton, and left traces of blood on trees and fences which were touched by the falling flakes. Chickens and hogs devoured it with evident relish. The heavens were clear, the sun shone, and only floating clouds were visible at the time, 2 p. m. Some of the flesh that was brought to Louisville was given to Professor Lawrence Smith, the well known scientist, who at first pronounced it animal flesh; but on further examination decided that it gave every indication of being the dried spawn of batrachian reptiles, doubtless that of the frog, which had been transported from ponds and swampy grounds by currents of wind, and had ultimately fallen on the spot where found.

Useful Information.

Lubricating Oils.

"A simple method for testing the hydrocarbons or mineral oils in lubricators is to fill a bottle with the oil in question, moistening the cork and inside the neck of the bottle, and then twisting the cork about its longer axis. The best lubricating oils produce no sound, but the more the oil is adulterated with hydrocarbons and products of dry distillation, the louder the noise produced. An oil that gives a loud cry is most unfitted for a lubricator."

Upon the above item, which has gone the round of all the scientific papers in the country, the *American Manufacturer* comments as follows: The method proposed is indeed "simple"—we have been submitting some oils to this test, not, of course, to prove the correctness of the test, for with the endorsement of all the scientific papers we should not presume to do that—but we find that we must change somewhat the estimate in which most oils have been held to make them conform to the standard set up in this simple test. A few examples will show what we mean.

Pure sperm produces no sound, therefore it is a good lubricant. Pure sperm mixed with an equal quantity of paraffine oil produces no sound, therefore it is as good a lubricant as pure sperm. Pure rosin oil produces no sound, therefore it is a good lubricant. Pure fish oil produces no sound, therefore it is a good lubricant. Coal tar produces no sound, therefore it is a good lubricant. Dowder's best spindle oil gives a "loud cry," distinctly heard at 100 feet distance, therefore it is "unfitted for a lubricant." Paraffine oil gives a distinct "cry," therefore it is a poor lubricant. (N. B. Paraffine oil is in general use either alone or "adulterated" with sperm in nine-tenths of the cotton factories in this country, and gives entire satisfaction, but then the "test" says it is not a lubricant.) Pure West Virginia oil gives a slight cry, therefore it is not as good a lubricant as petroleum residuum, which gives no sound, and is therefore a good lubricant.

We need not continue to record our tests. Every one who knows enough to handle a pen or a pair of scissors for a scientific paper must admit that the publication of such things only adds to the world's ignorance, not to its knowledge.

MAIZE AND NUTMEGS.—Most of our readers doubtless know that the nutmeg, like all other spice, grows in tropical countries. The fruit of the nutmeg tree, especially as it approaches maturity, is very like a large yellow peach. At maturity the outer hull opens, and if not gathered the valuable product would soon fall to the ground. The mace is the second coat which covers the nutmeg, and almost envelops the dark, impervious hull, or third covering of the nutmeg. When the product is gathered the mace is of a deep red color, and is taken carefully from the hull which still incloses the nut. Then the hull is broken and the nut taken out, when it is ready for market. In the palm days of the "Hon. East India company," all the company's possessions were governed by 24 gentlemen in London, called the "Hon. Court of Directors," who had spent their lives from early manhood to middle age in India, were usually the company's most distinguished civil and military servants, and were supposed to know everything pertaining to the interests of the great corporation. They superintended the sale of all Indian products, and, finding at one period that the mace sold more readily than the nutmeg, they wrote to the government in India to cultivate more of the mace and less of the nut!

LIGHTHOUSE WHITE-WASH.—The following are the ingredients which compose the white-wash sent out by the Lighthouse board of the Treasury Department, and which, it may reasonably be supposed, is the preparation which the best knowledge and fullest experience has selected from the many which are used for the purpose indicated: Slack one-half bushel of unslacked lime with boiling water, keeping it covered during the process. Then strain it, and add a peck of salt, dissolve in warm water, three pounds of ground rice put in boiling water and boiled to a thin paste, half pound powdered Spanish whiting and a pound of clear glue dissolved in warm water. Mix these well together and let the mixture stand for several days. Keep the wash in a portable furnace, and when used put it on as hot as possible with either a painter or white-wash brush. Thus prepared, this wash has been found, by experience, to answer on wood, brick or stone nearly as well as oil paint, and it is much cheaper.

HARDENING SPRINGS.—Get a piece of spring steel about the size of spring wanted; when forged end filed to tilt, make it warm red, immerse in spring water, dry the spring, then tie a piece of wire fast to the spring in any form, so as to hold it; dip in clean tallow or oil, put it on the fire until all the grease is burned off, and then swing round and round, as swift as you can, until cold.

A NEW MUCILAGE.—The *Journal de Pharmacie* states that if, to a strong solution of gum arabic, measuring eight and one-third ounces, a solution of 30 grains of sulphate of aluminum dissolved in two-thirds of an ounce of water be added, a very strong mucilage is formed, capable of fastening wood together, or of mending porcelain or glass.

BICYCLE VS. HORSE.—A ten mile race, between a fast horse named Happy Jack and a velocipede rider named Stanton, recently took place at Lillie Bridge, England, for \$250. For the first three miles the horse kept level with the bicyclist. The ground was rather sticky, owing to the late rains, for both, and Stanton seemed laboring, but this is his peculiar way of riding. Stanton was the favorite at as much as three to one, for the start allowed him was generally considered too much. For three miles the horse went easily; where he lost at the corners he made up in the straight. This style he kept up until the sixth mile, when his stride began to falter, not being ridden so well as on the last occasion, combined with the effect of the extra weight he was carrying. Stanton from this point gradually went ahead, and in the next mile he gained 50 yards. The horse was now beaten, and after going another lap was pulled up at eight miles. Stanton went on and finished the distance, 10 miles less 764 yards, in 34 minutes 34 seconds, being at an average velocity of nearly 18 miles an hour. He rode a 58 inch machine made by Keen, weighing 40 lbs. He seemed to have a good deal more in him had it been required.

SHARPENING EDGE TOOLS.—We copy the following recipe for sharpening edge tools from a German scientific journal, for the benefit of carpenters, machinists and laborers: "It has long been known that the simplest method of sharpening a razor is to put it for half an hour in water to which has been added one-twentieth of its weight of muriatic or sulphuric acid, then lightly wipe it off, and after a few hours set it on a hone. The acid supplies the place of a whetstone by corroding the whole surface evenly, so that nothing further than a smooth polish is necessary. The process never injures good blades, while badly hardened ones are generally improved by it, although the cause of improvement remains unexplained." The cause of this improvement is simply that those particles which are softer contain less carbon, are most attacked by the acids, and thus removed by them; while the harder particles—the more perfect steel—is richer in carbon, which causes it to resist the action of the acid better, and they remain. For the same reason, old rusty tools, when cleaned and sharpened, are always better than when they were new.

KEROSENE is making rapid advances against coal gas all over the country. The cost of oil light is about one-sixth the cost of gas light, and there is no doubt that it affords a far better light for the eyes. We do not see how the gas companies are to stem the tide that seems to set against them, except by adopting petroleum themselves and thus enabling themselves to reduce the price of gas to a point nearer the cost of oil light.

SOFTENING FILES.—Cover them with oil and hold them over the fire until the oil blazes; as soon as the flame runs all over the file, plunge it into the water. Or, put them into a moderate hot oven, for half an hour, if large files; but if small files, the first plan is the best.

Good Health.

Regulating the Bowels.

It is best that the bowels should act every morning after breakfast; therefore, quietly remain in the house and promptly attend to the first inclination. If the time passes do not eat an atom until they do act; at least not until breakfast the next day, and even then do not take anything except a single cup of weak coffee or tea and some bread and butter, or dry toast, or ship biscuit.

Meanwhile arrange to walk or work moderately for an hour or two each forenoon and afternoon, to the extent of keeping up a moisture on the skin, drizzling as freely as desired as much cold water as will satisfy the thirst, taking special pains as soon as the exercise is over to go to a good fire or very warm room in winter, or, if in summer, to a place entirely sheltered from any draft of air, so as to cool off very slowly indeed and thus avoid taking cold or feeling a "soreness" all over next day.

Remember that without a regular daily healthful action of the bowels it is impossible to maintain health or to regain it if lost. The coarser the food the more freely will the bowels act, such as corn (Indian) bread eaten hot, hominy, wheaton grits, bread made from coarse flour, or "shorts," graham bread, boiled turnips, or strabout, or grapes, or dried figs, or stewed tamarinds. A handful or two of raw or boiled chestnuts eaten during the day; a tablespoonful, more or less, thrice a day of white mustard seed swallowed whole, in water or otherwise; eating freely of parched corn; taking on rising a tumblerful of cream which has been allowed to stand until it has thickened, whether sweet or sour, are means which are sometimes successful in keeping the bowels acting freely once a day, without the necessity of taking medicine. When one fails to keep up a good effect, try another, in the hope that when the bowels have got into a habit of regular action it may be kept up by the judicious employment of such daily food as observation may show is best adapted to the object. The habitual use of pills, or drops, or any kind of medicine whatever, for the regulation of the bowels, is a sure means of ultimately undermining the health, in almost all cases laying the foundation for some of the most distressing

of chronic maladies. Hence, all the pains possible should be taken to keep them regulated by natural agencies, such as the coarse foods and exercises above named, or stewed prunes, or a glass of water on rising, into which has been stirred a teaspoonful of salt or a heaping tablespoonful of corn meal. Reliance on injections is disastrous eventually.

If the bowels act more than twice a day live for a short time on boiled rice, farina, starch or boiled milk. In more aggravated cases keep as quiet as possible on a bed, take nothing but rice, parched brown like coffee, then boiled and eaten in the usual way; meanwhile drink nothing whatever, but eat to your fullest desire bits of ice swallowed nearly whole, or swallow ice cream before entirely melted in the mouth; if necessary wear a bandage of thick woolen flannel, a foot or more broad, bound tightly round the abdomen; this is especially necessary if the patient has to be on his feet much. All locomotion should be avoided when the bowels are thin, watery or weakening.—*Hall's Journal of Health.*

The Scarlet Fever.

It is as unnecessary for a child to die of scarlet fever as it is that it should be blind with catarrh. Let us see: At any time before the body has finished its ineffectual struggle we are able to help it, not by wonderful medicines but by the knowledge of anatomy and the application of common sense. We consult the sympathetic nerve and do what it commands us to do. We must give this child salt when it wants it; we must give it acid when it has fever—not vinegar but lemon juice, because the first coagulates albumen and the latter does not, on account of the surplus of oxygen which it contains. To imitate the soothing mucus in the intestines, which is now wanting, and to give some respiratory food at the same time, we add some gum arabic. To restore and relieve the injured nerve we apply moist warmth. In practice we can fulfill all this with the following simple manipulations:

Undress the child and bring it to bed at the very first sign of sickness. Give it, if it has already fever, nothing but warm, sourish lemonade with some gum arabic in it. Then cover its abdomen with some dry flannel. Take a well folded bed sheet and put it in boiling hot water; wring it out dry by means of dry towels and put this over the flannel on the child's abdomen. Then cover the whole and wait. The hot cloths will perhaps require repeated heat. According to the severity of the case and its stage of progress perspiration will commence in the child in from 10 minutes to two hours.

The child then is saved; it soon falls asleep. Soon after the child awakes it shows symptoms of returning inclination for food; help its bowels if necessary with injections of oil, soap and water, and its recovery will be as steady as the growth of a green-house plant if well treated. Of course if the child was already dying nothing could save it, or if it has effusions in the lining of the heart or brain it is much better that it should die. But if the above is applied in due time, under the eyes and directions of a competent physician, I will guarantee that not one in a hundred children will ever die of scarlet fever.

I know this will startle some of my readers, especially those who have lost children already, but I shall go still further. I maintain that a child will never get scarlet fever if properly treated. If a child has correctly mixed blood it will not catch the disorder if put in bed with a sick child. This is still more startling, but nothing is easier of proof.—*Good Health.*

Beds and Bedrooms.

Never use anything but light blankets as a covering for the sick. The heavy, impervious cotton counterpane is bad, for the reason that it keeps in the exhalations from the pores of the sick person, while the blanket allows them to pass through. Weak persons are invariably distressed by a great weight of bed clothes, which often prevent their getting any sound sleep whatever. It is better to sleep in a cool room and dress in one that is well warmed, than the opposite. If it is necessary to heat the bedroom, let it be by means of an open grate fire, rather than by a register or flue.

In view of the fact that most people pass one-third of the 24 hours in bed, the importance of having only the best bedding needs no argument. There is no wisdom, therefore, in buying cheap or second-class articles for the sleeping room, but true prudence directs to get the very best bedding that your means will command; a first-class hair mattress will outlast two of inferior quality. The same difference will also be found in respect to feathers, and with the latter as with hair, the best is always cheapest. Too many young housekeepers neglect to follow this rule, and pursue a penny-wise and pound-foolish policy, when they might just as well have adopted the opposite practice.

SCARLET FEVER.—In this disease the parent and the school teacher are often concerned to know how long a time must elapse before it is safe to admit the convalescent children to mingle with other children. And the answer is, that for a month, at least, the body of a scarlet fever patient is casting off scales from the skin, and from the nose, throat, bowels and kidneys discharges which are poisonous and convey the disease. The chief danger, however, arises from the skin, as this is the main outlet for the blood poison to escape; hence every scale it throws off can carry the infection.

Domestic Economy.

Cooking Carrots.

It is a notorious fact, says the *Boston Journal of Chemistry*, that we Yankees, like our English cousins, are lamentably unskillful in cooking vegetables, which the French serve up in such an endless variety of delicious forms. In the country, where fresh vegetables can be had so easily, they are even worse treated than in the city. In fact, they are usually cooked for the family just as they are for the cattle and the pigs. There is no more thought in the one case than in the other of making them savory as well as wholesome. We have before given some excellent foreign recipes for cooking potatoes, which with us are almost invariably boiled or fried, and abominably in either case. We now select from the *London Garden* some hints for cooking carrots, which the average Yankee housewife never thinks of serving in any other way than "plain boiled." The contributor has tested all these, and vouches for their merit:—

CARROT SOUP.—Take one and a half pounds of carrots which have been first brushed very clean, then boiled, until tender, in slightly salted water; mash them to a smooth paste, or rub them through a sieve; mix the paste with two quarts of boiling soup (strong beef broth will do); season this with pepper and salt, and add, before being finally boiled up, a small lump of sugar and a piece of butter. Serve with a dish of bread cut into small dice and fried in butter.

CAROTTES A BEURRE.—Boil sufficient carrots for a dish until they are quite tender; drain them well, and whilst this is being done, dissolve from two to three ounces of butter in a saucepan, and strew in some minced parsley, some salt, and white pepper or cayenne; then add the carrots, and toss them very gently until they are covered with the sauce, which should not be allowed to boil. Cold carrots may be rewarmed in this manner.

STEVEN CARROT.—Half boil a half dozen large carrots without cutting them; then slice them into a stewpan; put in enough good stock to nearly cover them, with pepper and salt to taste. Stew them till tender; then mix in a separate vessel half a pint of cream and a tablespoonful of flour, and add to the carrots with one ounce of butter. Boil up and serve. Small young carrots may be dressed in the same manner, and will, of course, require less time to cook them.

CAROTTES A LA MARIÉE D'HOTEL.—This is a genuine French recipe. Scrape twenty small young carrots and wipe them, but do not wash them. Put them into a pan with six ounces of fresh butter; cover the pan and toss the carrots over the fire from time to time. After a quarter of an hour add salt and pepper, a chopped onion and parsley. Cover the pan and gently toss it again from time to time, until the carrots are tender. If you use large carrots, cut them into slices and boil them in water until they are nearly done. Drain and finish them as above.

CAROTTES A LA POULETTE.—Take some young carrots; scrape and wipe them carefully. Put them in a pan over a moderate fire, with six ounces of butter and a tablespoonful of flour; toss them repeatedly, and take care the flour does not become brown. Pour a tumblerful of milk into the pan, cover it and let the carrots simmer slowly until they are done. Then take the pan from the fire, and pour into it two yolks of eggs, mixed with a tablespoonful of good cream, and a little pepper and salt; warm these ingredients, taking care not to let them boil, and serve.

CAROTTES AU JAMBON.—Put into a pan six ounces of butter and a tablespoonful of flour; simmer these over a quick fire, until they become slightly brown. Add a gill of boiling water, then six ounces of raw ham cut into small dice, a little salt and pepper, a bay leaf, a small bunch of thyme and parsley, a large onion, and six large carrots cut into slices the size of a half crown. Cover the pan, and let the carrots boil until they are done. Then take out the seasoning, and serve. This recipe also answers well for turnips.

SPLIT PEA SOUP.—Take any bones of roast meat, lay them on a clean meat board, pound and break them, (a small hatchet carefully wiped clean is very good for this purpose). Put the bones and any trimmings of cold meat into a soup kettle or a large saucepan, cover well with cold water, set it on the back of the stove, cover it closely. When it first bubbles, skim it well, cover it, and let it simmer slowly four hours. If necessary to prevent it from boiling hard, set a tin plate on a brick under the saucepan. At the end of four hours take the soup from the fire, pour off the liquor through a strainer or colander into a shallow pan, let it become cold, then remove every particle of fat from the surface, and strain the soup through a cloth. An hour before it is wanted, put it on the stove to heat. Allow for three pints of stock, a large coffee cup full of split peas, which should be soaked if very old. Pour off those which rise to the top, put the others on the stove to boil for two or three hours, until they are perfectly soft. Then rub them through a colander, and when the stock is boiling, add the peas, and a small piece of butter, end pepper and salt. This soup is good and nourishing, besides being very economical. Excellent broth and soup can be made of bones left from roast meat of any kind, and they should be saved for the purpose.

MINING SCIENTIFIC PRESS

W. B. EWER..... SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, GEO. H. STROGO
W. B. EWER, JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner
of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week, 1 month, 3 months, 1 year.
Per line..... 25 50 \$4.00 \$5.00
One-half inch..... \$1.00 3.00 7.50 24.00
One inch..... 1.50 4.00 12.00 40.00

Large advertisements at favorable rates. Special or
reading notices, legal advertisements, notices appearing
in extraordinary type or in particular parts of the paper
inserted at special rates.

SUBSCRIPTIONS payable in advance.—For one year, \$4;
six months, \$2.25; three months, \$1.25. Remittances
by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send to
their respective to the Press promptly as regularly as
the year comes round. It saves us much expense to
commissioners for collections and renewals. May we not
request more of our good patrons to do so!

BE MORE PARTICULAR.—We can only make the
changes requested by the following parties on our
mail list, when they, or some one else, send us their
P. O. address. Otherwise we would have to look over
from 1,000 to 10,000 names. Frank Becker, O. Seawell,
L. Boyer, M. Lewis, F. Anson, and Antonia Byros.
We also want the address of Wm. Buck.

UNKNOWN.—We have lately received cash at this
office without due explanation, as follows: From Car-
son, Nev., \$4, by express.

The senders will please give full address, date of
sending, etc.

THE ORIGINAL ARTICLES in this paper are mostly set
in solid type, giving to our columns one-third more
reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, April 1, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A New Motor; Con-
solidation of Mining Companies, 109. Tellurium;
Notices of Recent Patents; A Higher Education, 118.
Gems and Precious Stones; Center Draft Tongue for
Reapers; Patents and Inventions, 117.

ILLUSTRATIONS.—The Rider Compression Eol-
ogies, 109. Center Draft Tongue for Reapers and
Mowers, 117.

THE ENGINEER.—Carrying the Sea to Island
Cities; An American Engineer's Triumph; Mechani-
cal Engineering; The American Institute of Mining
Engineers, 210.

SCIENTIFIC PROGRESS.—The Temple of Belus
—Some Interesting Discoveries; An Interesting Ex-
periment; Ocean Currents; The Electric Light in
Paris; Interior Constitution of Magnets, 211.

MECHANICAL PROGRESS.—Our Iron Indus-
try; The Iron Works of the United States; New Cast
Machinery; The Length of Rails; Pumping
Engines for the Water Works at Hull, England, 211.

MINING STOCK MARKET.—Sales at the San
Francisco and Pacific Stock Boards; Notices of As-
sessments; Meetings and Dividends; Review of the Stock
Market for the Week, 212-13.

MINING SUMMARY from various counties in
California and Nevada, 213-14-20.

USEFUL INFORMATION.—Lubricating Oils;
Mace and Nutmegs; Lighthouse White Wash; Hard-
ening Springs; A New Mucilage; Bicycle vs. Horse;
Sharpening Edge Tool; Softening Flies, 215.

GOOD HEALTH.—Regulating the Bowels; The
Scarlet Fever; Beds and Bedrooms, 215.

DOMESTIC ECONOMY.—Cooking Carrots; Split
Pea Soup, 215.

GENERAL NEWS.—General News Items and
Miscellaneous Paragraphs on 217 and other pages.

MISCELLANEOUS ARTICLES.—Horse Shoes;
Contraction of the Earth; A Car Load; The Gatling
Gun Improved; Tea—Its Culture in California, 210.
Mining and Mining Down the Creek; Silver Colo-
rations; The Value of Silver Savings;
The Kentucky "Flesh Show"; 214. The Cause of
Hard Times, 218. Fence Coal Mine, 222.

NEW ADVERTISEMENTS.

New England Tunnel and Smelting Co.—Sale; Notice,
Geo. Ginn, Belmont, Nev.

PACIFIC IRON WORKS.—A very heavy casting
was made at the Pacific iron works this week,
in the shape of the large cylinder for a com-
pound engine, which is being built for the
pumping machinery of the Savage mine, on the
Comstock. The cylinder is 48-inch bore and
eight feet stroke, weighing sixteen tons. The
engine is a compound one, with the Davy differ-
ential valve gear, worked by an independ-
ent cylinder. With this machinery goes a
line of 13-inch pumps and two sets of pump
boots; the pump column reaching to the 2200-
foot level of the mine. We shall shortly give
a detailed description of this fine machinery.

The Truckee Indians have made affidavit
that it would cost \$500,000 the first year and
\$50,000 thereafter to consume their own saw-
dust or otherwise so use it as to keep it out of
the stream; hence they claim that it is better
the trout should die than the sawdust kill them.

ONE hundred and fifteen car loads of ore per
day is the average shipment from the Com-
stock mines to the Silver City and Carson iron-
mills.

The crowded state of our advertising columns
just at present prevents our publishing the
usual amount of reading matter.

Tellurium.

Considerable excitement has been raised by
certain interior papers of this State, by the an-
nouncement of the discovery of tellurium, and
the statement that it was worth \$3,000 per
pound. In several counties in the interior this
has set a number of prospectors at work, with
the expectation of making a fortune in a very
short space of time, before the supply should
be so increased as to reduce the price. Num-
bers of samples of ore, supposed to contain
tellurium, have been sent to assayers in this
city and elsewhere, by sanguine claim-holders,
who think they have a good thing. We are
sorry to dispel the illusion as to the value of
the article; but are, at the same time, happy
to avail ourselves of the opportunity to explain
to our mining friends, who may be making
foolish ventures, exactly what tellurium is, how
to test its presence, and how much it is worth.
With this object in view, we interviewed Mr.
Henry G. Hanks, the well known chemist and
assayer of this city, who gives us the following
information concerning the substance:

Tellurium is a white metal, brittle and easily
fusible. Its equivalent or combining weight is
64.2 in the old system of notation, which is
doubled in the new. The symbol used by
chemists to express this element is "Te."

Tellurium was discovered and named by
Klaproth. The specific gravity of the metal is
6.257.

The name tellurium is derived from the
Latin word "Tellus," the earth. The word
"tellurio" has no reference to the metal, but
implies, pertaining to the earth.

This metal is very rare on the earth, but
exists in a gaseous state, probably combined
with hydrogen, in the atmosphere of some of
the fixed stars, as revealed by the spectroscope.
It is particularly noticeable in Aldebaran.
I think I am not mistaken in stating that it has
not yet been discovered in the sun.

Tellurium, as far as known, is found only in
ten rare minerals, as follows (the figures show-
ing the percentage of tellurium in each):

1. Altaite, combined with lead.....	38.3
2. Calaverite, combined with gold and silver.....	56.0
3. Hessite combined with silver.....	37.2
4. Joesite, combined with sulphur, selenium and bismuth.....	15.93
5. Nagyagite, combined with sulphur, lead, silver, gold and copper.....	30.52
6. Petzite, a variety of hessite (No. 3).....	
7. Sylvanite, combined with antimony, gold, silver and lead.....	44 to 60
8. Tellurium, native, nearly pure.....	
9. Tetradyomite, combined with silver and bismuth.....	33 to 43
10. Tellurite, doubtful.....	

Tellurium is not only fusible, but is volatile,
and may be sublimed in a glass tube without
change. When exposed to high temperatures it
becomes oxidized to tellurous acid (TeO₂),
giving off dense white vapors. If the experi-
ment is made in a piece of clean charcoal before
the blow pipe flame, a coating is formed on the
coal. If this coating is touched by the point
of the reducing flame, it disappears, tinging
the flame at the same time bluish green. This
reaction is characteristic. Any substance con-
taining tellurium imparts a red color to boiling
concentrated sulphuric acid. By these tests,
tellurium may be detected with certainty in any
substance which may contain it.

The statement lately made in the papers, that
a firm in San Francisco had paid \$3,000 for
one pound of tellurium, is evidently a mistake.

At the rate of 51 cents per gram—at which
price it is quoted in German price lists—a
pound would only be worth \$231.54. But when
it is known that dealers make large discounts
on their printed list of prices, and that whole-
sale rates are much less than retail, it is evident
that so large a quantity as a pound could be
bought for a much less sum.

Tellurium has absolutely no use in the arts.
It is only prepared in small quantities as a
chemical curiosity. All the reactions of the
metal can be obtained by students from some
of the minerals containing it, which are com-
paratively cheap. Like every other manufac-
ture, its production is governed by the laws of
supply and demand. In this case both the
supply and demand are small; hence there is
no inducement for its production, and those
who do produce it naturally realize all they can
from their small sales.

As an illustration of how the price of a
commodity decreases when inducements are
offered for its large manufacture, I have only to
cite the metal sodium, which a few years ago
was very high-priced for the same reason that
tellurium is at the present time, although the
supply was enormous, the dispersion of sodium
being greater than that of almost any other
substance. When the demand increased—it
being required for the manufacture of sodium
amalgam, and for the reduction of aluminum—
new methods of producing it were discovered,
and it has now become quite cheap and abun-
dant.

Tellurium is found in considerable quantities
in Schenitz, Hungary, and in the silver mine
of Sadoivinski in the Alai, associated with sil-
ver and lead. At the mine "Maria Loretto"
in Transylvania, in sandstone, with quartz,
pyrites and gold. From this locality (Transyl-
vania) the name "sylvanite" is derived.

In the United States it has been discovered in
Virginia and North Carolina associated with
bismuth (tetradyomite).

Fine specimens come to us from the Ameri-
can mine, Sunshin district, Boulder county,
Colorado.

In our own State it is not rare, being found
in considerable quantities in several localities.
The Melones mine, Calaveras county, is a
celebrated locality. Splendid specimens of cala-
verite, hessite, sylvanite and native tellurium
associated with gold have been shown in this
city. The Golden Rule, Tuolumne county, pro-
duces fine species of hessite and petzite. The
R.W. Hyde Ranch is another locality.

According to Dana, petzite and calaverite
have been found at the Stanislaus mine in
Calaveras county.

Metallic tellurium is principally obtained
from the telluride of bismuth (tetradyomite).
The ore is first washed to concentrate it, then
mixed with an equal weight of carbonate of
soda or potash. The mixture is then made
into a paste with olive oil, and heated in a
closed crucible, first gently, to prevent froth-
ing, then at a high heat. The fused mass is
digested in water, which dissolves out the tel-
luride of soda or potash, giving a deep wine
colored solution. The bismuth and the char-
coal resulting from the burning of the oil re-
main behind.

If the liquid is allowed to stand exposed to
the air, the tellurium gradually precipitates
until it has all separated. This precipitation
can be greatly accelerated by blowing air
through the solution.

The precipitated metal is purified by wash-
ing in dilute acid and distilling in an atmos-
phere of hydrogen.

Notices of Recent Patents.

Among the patents recently obtained through
Dewey & Co.'s SCIENTIFIC PRESS American and
Foreign Patent Agency, the following are
worthy of mention:

IMPROVEMENT IN NICKEL PLATING.—Camillo
Maggio and Giuseppe Maffiola. These inven-
tors patent certain improvements in the art of
plating with nickel upon other metals. The
improvement consists, first, in the preparation
of the metal to be plated in such a manner as
to prevent rust or oxidation; and secondly, in
a new solution, by which they are enabled to
deposit the metal more perfectly and upon
metals which it has hitherto been impracticable
to protect with nickel. It is well known that
in the process of electro-plating the metal is de-
posited in the form of minute grains, and when
the metal is malleable, as in the case of gold
and silver, these grains are welded or united in
the process of burnishing so as to completely
cover and protect the whole surface; but when
nickel is deposited in this manner it cannot be
made to protect the surface any more com-
pletely than is done by a simple deposition of
the particles, on account of its brittleness, which
does not admit of burnishing. The surface
beneath is, therefore, more or less exposed to
the action of air, acids or other substances, and
will in time become oxidized or corroded in
spots, especially in the case of iron, steel, lead,
copper and other base metals. These inven-
tors overcome this difficulty in a very simple
manner. They are also able to deposit nickel
on zinc successfully by the use of a peculiar
bath.

REAPER.—David P. Russell, Dixon, Solano
Co. The object of this invention is to provide
a "header" with an automatic grain receptacle
and dropper so that it can be used as a reaper
by collecting the cut grain in the receptacle
until a sufficient quantity has accumulated to
form a bundle, and then dropping it. The in-
ventor simply makes a box attachment to the
elevated end of the draper, from which the
grain ordinarily falls into the header wagon,
and the bottom of this box is operated automa-
tically by gearing connected with the driving
mechanism of the machine, so that it will at
intervals open and close. The cut straw or
grain is carried by the draper and delivered into
this box, where it is retained, until a sufficient
quantity is collected to form a "gavel" or
loose bundle of grain, when the bottom of the
box opens and drops the gavel upon the ground.
Thus enabling farmers to utilize their headers
as reapers and do the work with a great deal
more celerity than with the ordinary reapers,
at the same time leaving the grain in gavels
ready to be bound.

IMPROVED WINDMILL.—John Brower, Perry
D. Reed and Jasper C. Reed, Colusa, Cal.
This invention relates to improvements in that
class of windmills which are made adjustable
by means of vanes or sails, which can be turned
about an axis, so as to throw them more or less
out of the wind. It consists in a series of ra-
dial arms, which are connected with the vane
sections by suitable rods. These radial arms
are mounted on the end of a shaft, and have a
motion longitudinally, so that it is drawn for-
ward when the wind throws the vanes back,
and a weight or spring draws it back as the
force of the wind decreases. When the wind
blows strongly the vanes will be thrown back-
ward more or less and the rotation of the wheel
regulated. When the force of the wind abates,
the weight or spring will draw the shaft back
again and return the vanes to their position.

Mrs. SANDY BOWERS, the Washoe seeress, has
closed her eyes again and now solemnly pre-
dicts another life destroying calamity for Vir-
ginia and the tapping at no distant day of a
subterranean river in the header of the Suto
tunnel.

REPORTS from the Black hills are discourag-
ing.

Higher Education.

The following is an abstract of a lecture on
the above subject, delivered by Professor
Joseph Le Conte, at the University of Califor-
nia, on Friday of last week.

My subject is higher education, old and new.
It is the subject of the age, not only of this time
but far more than this, of all times. It has no
interest in the passing questions of the day or
so-called "live questions," which rise to the
surface like bubbles, display their beautiful
colors, burst, and pass away. Hence it is not
a question of times, but of all time, a living
question. It is the basis of civilization and
more important at every step of education. It
is important now, because we are passing from
the much revered old to the new education. In
attempting to adjust this transition I am at
once placed in the knowledge of the dilemma,
that the time is insufficient. Hence, I must
choose between an address appealing to your
feelings, or a plain statement of facts. But I
must lay aside ornament, strip off this clothing,
dissect away and dwell upon the bare skeleton
of truth. We may, however, be sure that there
is a rich vein of marrow running through these
dry bones well worth the time employed in dis-
cussing.

Education is a preparation for active life. In
later times a discussion is growing up in re-
gard to higher education unfitting men for life.
There are grounds for this theory. Higher
education originated in the revival of learning
after its sleep during the middle ages. This
system of education was admirably adapted for
the study of ancient languages and books. It
gradually grew up into a system of intellectual
culture not equalled. There has been a prodi-
gious advance in sciences of nature and conse-
quently an advance in the departments of ed-
ucation. This learning is not recorded in hu-
man characters but in the hieroglyphic system
of nature—not found in books but in nature, of
which science holds the key. There has been a
graft upon the old branch, a teaching of a new
subject by old methods which is but imper-
fectly successful. Thus two classes which are
irreconcilable have arisen, one clinging to old
methods and the other, knowing that education
must be a preparation for life, would absolutely
wipe out old and introduce new methods. One
class are men of culture, the other men of prac-
tical business. One deals mainly with men,
the other with things. One seeks to elevate
men, making them nobler, the other to make
education a mere apprenticeship. The one is
the medievalist, the other the utilitarian. I
will show that both are right, and that both
are wrong. Each is right from his own stand-
point, and each is wrong by excluding the
other's views. Education is the preparation
and training for eminent success in life. Hence,
any scheme of education is of utility in pro-
portion as it prepares for this end. But we
must use life and utility in the widest sense,
life including moral as well as physical, spiri-
tual as well as temporal.

But now the term life is limited. We es-
timate men by the quantity of money they pos-
sess, we speak of a man's being worth so much.
Utility is also restricted in common language,
so we must use another term—culture. Educa-
tion has two ends and therefore there are two
kinds of education—first, general or liberal ed-
ucation, tending to elevate men in every re-
spect, and second, professional education as
preparation for special pursuits. I now wish
to show that these are not antagonistic but con-
secutive. The second grows out of the first by
the natural law of evolution. They may be
compared to a tree, the trunk of which repre-
sents culture and the fruit bearing branches
the special professions. Each one alone de-
feats its own objects. Culture alone fails to
prepare us for active life, while professional
education not only fails to develop us to
highest manhood, but also fails to fit us for
practical work when accompanied with culture.

In order to be useful, the tree must not only
have a trunk but also branches. The tendency
of culture is to disregard the professional study,
and hence becomes nearly useless. I maintain
that the two should be consolidated, but all do
not think so. We should not reject this ideal
because we cannot attain to it, for we are guilty
of meanness by rejecting it on this account. A
scheme of education is good in proportion as it
is natural. Nature has two modes of working
—external nature atrems in through our
senses, and we send back our knowledge in the
form of power; our fellow man acts upon us by
the means of language. The one is nature cul-
ture, and the other knowledge culture. The
first is the power over nature, and the other
over men.

Our system of education must have two
courses—First, nature course, and second, lan-
guage course. The phenomena of our spiritual
nature is so difficult to understand, that a third
class is necessary—human mind. Higher ed-
ucation is of two parts—college education and
university education. The object of the first is
culture for the sake of culture, and that of the
second is to concentrate our power to special
and higher ends. Every scheme of the higher
education includes three courses—First, scien-
tific; second, philosophical, and third, lan-
guage. The scientific course gives some truth,
and cultivates our love and ardor to strive for
truth. It goes up through the lower sciences to
the highest, which is social science. It gives
coarse but whole-some food. The philosophical
course gives strong muscular exercise to the
intellect, heats the intellectual blood and stimu-
lates the intellectual nerves. It passes from

logic through like sciences, till it also attains to social science. It may furnish food for gods, but not for man. The language course is the embodiment in sensible form of our innermost thoughts, either in speech or in writing. It commences with ancient languages, passes through modern languages, literature, art, history, and on till it approaches social science. At first they are widely separated, but gradually converge, and meet on the great plane of human civilization. Neither the first or the second are co-ordinate, but the third is co-ordinate, in thought and expression, when one gives and the other receives. There are two great loves of mankind—love of God and love of man. By one we reach above and commune, as it were, with Deity; by the other we shed light on our fellow man. We receive divine instruction and give it out again to man.

It is truly said "it is more blessed to give than to receive." This is cultivated by the study of language. In physical science we have physical force. In chemical science we have, in addition, chemical force, and so on up the scale. In lower science we have the methods of deduction, and the higher we go the more we find the use of the methods of induction and generalization, until in the highest science we have only induction. The one tends more to special ends.

Thus we may compare this culture to a temple of many stories, consisting of a large main building with two wings. The first class of teachers, the medievalists, lay the foundation only. The second class, the materialists, build only one wing. The first is worse, because their structure is of no practical use. If common schools are the roots of the tree of education, and colleges the trunk, universities are the fruit-bearing branches. There is a sort of gap between educational life and practical life—one tends to the abstract, the other to the concrete. In the lower grades, practical life and education differ but little, but the higher we go the farther they diverge. At the bottom it is very easy to step from the grammar school to active life. It is more difficult to step from the high school to active life, but when in college the transition is very difficult indeed, and in some cases impossible.

The very object of the university is to bridge over this chasm, to build a bridge from the higher branches of education to the higher branches of professional life, law, theology, medicine, civil engineering, education, chemistry, etc. This idea is not realized in any part of the earth, but is approached, perhaps most nearly in the German universities. They are still too far on the side of the medievalists and only recognize three liberal professions, law, theology, and medicine. The technical schools are separated from the universities. It seems to me that the conception in an embryonic condition is more fully realized in our university than in any other. The branches are budding and have not yet flowered. Last of all, a university is essentially a cluster of colleges. Shall we then have the general culture pursued in the University? Yes, but culture must be for culture's sake, and also for the professional scholar and thinker. Another object of culture is, that it ennobles all professions. It brings them into communion with one another. The university has a higher trunk, but also more fruit-bearing branches. The trunk of general culture must pass through the branches of special studies and appear at the top as a preparation for the nobler life.

Center Draft Tongue for Reapers.

The accompanying engraving represents Fassig's center draft tongue for reapers and mowers. The arrangements of this tongue are such that while the horses are hitched near the machine as in the old tongue, yet they pull on the center pivot which passes through the tongue near the front end, and the double-trees having a lateral sliding motion, can adapt themselves to either side of the main tongue, and thus equalize the draft in all conditions and positions of the machine.

A is the stationary tongue and B the center draft tongue joined to it by the center pivot, C. The spring, E, keeps it in position when drawing directly ahead. The point of resistance being on the pinion near the front end of the tongue, keeps it perfectly still and renders it impossible to chafe the necks of the horses; and by the lateral motion of the double-trees they so adjust themselves as to greatly assist the horses in turning the machine at the corners of the field. The side draft is controlled perfectly, and there is no jarring or jolting in the horses or machine. A faller swath can be cut and the machine is turned one-half easier. Any farmer can see the advantages of this center draft tongue without having them pointed out to him. The manufacturer is Jacob Keady, New Pittsburg, Wayne county, Ohio. He offers for sale the right for California.

WORK RESUMED IN THE COAL REGIONS.—Of the collieries owned by the Philadelphia and Reading coal and iron company, twenty have resumed work. Recent rains will interfere with work to a small extent for several days. In the vicinity of Shenandoah, all went to work except at the Kohinor and Turkey Run mines, where, because of a reduction of the contract work, some of the miners have struck.

No white man ever saw so much snow as there is now to be found in the Sierras.

Gems and Precious Stones.

(Written for the Press by HENRY G. HANKS.)

(Continued from last week.)

A.—Diamond, Jet and Cannel Coal.

The name diamond is a corruption of "adamas" or "adamant," derived from two Greek words, meaning "I conquer," referring to its excessive hardness.

The early history of the diamond is obscure. There seem to have been stones of quite different nature known to the ancients as "adamas." Pliny says: "Adamas is a mineral which for a long time was known to kings only, and to but few of them. The ancients supposed that adamas was only to be discovered in the mines of Ethiopia, between the temple of Mercury and the Island of Meroe, and they have informed us that it was never larger than a cucumber, or differed at all from it in color."

It is very certain that Pliny knew but little of the matter, for he describes six varieties, all of which, according to his description, possessed properties not found in the diamond, but he becomes absurd when he says that the diamond "which resists every force of nature, is made to yield before the blood of a he goat." To those who desire to verify this reaction he gives the following advice: "The blood, however, must be warm; the stone too, must be well steeped in it, and then subjected to repeated blows."

Allusions met with in ancient Hindu mythology lead to the supposition that they were in possession of gems and held them in high estimation.

According to Jewish history as set forth in the Bible the diamond was one of the 12 gems set in the breast-plate of the high priest. But to my surprise I find that Josephus denies this

Hydrabad and Masulipatam. Other localities in India have produced large quantities. It is said that Sultan Mahmood, when he died, left 400 pounds of diamonds. These diamond fields are now exhausted and seldom produce any stones of value.

Diamonds were discovered in Brazil in 1728. They had always been thrown aside as useless in gold washing, until one who had seen this gem in the rough state quietly collected a large quantity of them, from the sea of which, in Portugal, he realized a fortune.

They are found in an alluvial soil, in the district of Cerro di Fria, Minas Geraes, San Paulo and in other localities. Those Californians who have visited Rio Janeiro will remember the gorgeous display of diamonds in the shop windows—the product of these mines. It is said that Brazil has already produced two tons of diamonds.

Only a few years ago the discovery of diamonds in Africa startled the world. It was thought that the price of these gems would be seriously affected by the quantities thrown on the market, but such was not the case. The African diamonds did not prove of fine quality.

When the Brazilian diamond fields were opened, it was not believed in England; but it was thought that the Indian diamonds had been sent to Brazil, and from thence sent to England.

The mines of Borneo have produced but few large diamonds, but great quantities of small ones. 2,000 carats is the amount of annual production credited to that island.

It is estimated that out of 10,000 diamonds only one will be found weighing 10 carats. Any diamond of this weight is called "princely."

There are only five diamonds which are rec-

CENTER DRAFT TONGUE FOR REAPERS AND MOWERS.

indirectly. As the discrepancy is remarkable I have given both:

BIBLE.	JOSEPHUS.
1 Sardius.	1 Sardonyx.
2 Topaz.	2 Topaz.
3 Carbuncle.	3 Emerald.
4 Emerald.	4 Carbuncle.
5 Sapphire.	5 Jasper.
6 Diamond.	6 Sapphire.
7 Ligure.	7 Ligure.
8 Agate.	8 Agate.
9 Amethyst.	9 Amethyst.
10 Beryl.	10 Chrysolite.
11 Onyx.	11 Onyx.
12 Jasper.	12 Beryl.

It will be seen that in the list given by Josephus that the arrangement is different, and that the chrysolite replaces the diamond. According to the Bible the diamond was one of the precious stones worn by the king of Tyre.

History shows that the ancients attributed great medicinal powers to gems. They were worn also as a protection against all forms of evil, some in a vague general way, while others were regarded as antagonistic to special diseases or accidents.

Pliny claims for the diamond that it will "overcome and neutralize poisons, dispel delirium and banish groundless perturbations of mind." Less than a century ago diamonds were borrowed from rich families to act as a cure for certain diseases. It is said that to prevent them being swallowed by the patient they were secured by a string when placed in the mouth.

Pinto and Pythagoras must have known something of gems and crystals, as they have beautifully written how "Nature in the dark recesses of the earth occupies her time in working out geometrical problems."

It is an historical fact that when during the French revolution the diamonds of the rich were given over to the people, it was found that many of them were imitation.

Until quite recently the chemical composition of the gems and crystals, as they have beautifully written how "Nature in the dark recesses of the earth occupies her time in working out geometrical problems."

As soon as its chemical nature was discovered attempts were made to produce it artificially in the laboratory, but up to the present day without success.

The first diamonds came from India. The famous mines of Golconda are situated between

ognized as "sovereigns," which will be mentioned hereafter.

There have been two panics in the price of diamonds: The first when it was known that Brazil was producing large quantities of this gem, and the other at the time of the French revolution. At these periods the prices of diamonds fluctuated in the strangest manner. The discovery of the African diamond fields did not cause any great fall in prices as was expected.

The first diamond was found in South Africa, in March, 1867. According to Prof. Tennant, 10 per cent. of the Cape diamonds are first-class, 15 per cent. second class, 20 per cent. of the third; the remainder being of the quality known as *borf*, and are useful only to cut other diamonds, and for glaziers' diamonds, rock drills, etc. According to the same authority, the Cape has already produced diamonds to the value of £12,000,000.

(To be Continued.)

THE MECHANICS' FAIR.—The Board of Managers of the Tenth Industrial Exhibition under the auspices of the Mechanics' Institute met Monday evening and adjourned *sine die*. Immediately after the adjournment the Board of Managers for the next exhibition organized by the election of the following named gentlemen: A. S. Hallidie, President; P. B. Cornwall, Vice-President; Henry L. Davis, Treasurer; J. H. Culver, Recording Secretary; James Spires, Corresponding Secretary; J. H. Gilmore, Superintendent; James C. Patrick, George Spaulding, D. E. Hays, H. S. Smith, James Drury, Asa R. Wells, Charles Eliot, J. B. Stetson, J. H. Stoutenborough and Jeremiah Browning. These gentlemen constituted the Board of last year, with the exception of Messrs Stetson and Drury, who were elected vice R. B. Woodward and W. P. Stont, resigned. The rules and regulations of the last fair were adopted. The board, in a preliminary announcement, state that the next exhibition will be opened at 11 o'clock A. M. on the 8th of August, and continue open at least one month thereafter. The management is specially anxious to have this year a good display of mineral products, and urge all interested in that branch of business to assist as far as possible.

There are no less than 10,000 men in the Black hills.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch, Dated Washington, D. C., Mar. 28th, 1876.

FOR WEEK ENDING MARCH 14TH, 1876.

HYDRAULIC HOIST.—Samuel Ronuda, S. F., Cal.

NICKEL PLATING.—Camillo Maggio and Giuseppe Maffiella, S. F., Cal.

WINMILL.—John Brower, Perry D. Reed and Jasper P. Reed, Colusa, Cal.

ROTARY PLOWS.—William H. Foye, S. F., Cal.

STEAM BOILER FURNACES.—Michael Lufenberg, S. F., Cal.

PROPELLERS FOR VESSELS.—Thomas M. Rankin, Modesto, Cal.

REISSUE.

ELEVATOR.—Philip Hinkle, S. F., Cal.

TRADEMARK.

MUCILAGE.—Joshua Z. Dickson, S. F., Cal.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

General News Items.

YELLOW FEVER is prevalent in Rio Janeiro. The Hudson river is still blocked up with ice.

RECENT storms in New England have caused great damage.

THE floods have destroyed a large portion of the crops in southern France.

THE sugar crop of Cuba will be \$30,000,000 less than that of last year.

THERE are 33 investigations under way before the Congressional committees.

WIFE heaters in California are now punished at the whipping post.

ELEVEN hundred new buildings were erected in the city last year.

PIPER, the Boston sexton, convicted of the murder of Mabel Young, has been sentenced to be hanged.

THE rinderpest has broken out in Japan among the cattle.

ACCORDING to Langley's new directory, we have a population of nearly 270,000 in San Francisco.

A STEAMSHIP load of articles for the Centennial from Rio Janeiro has arrived at Philadelphia.

A BILL has been signed by the Governor prohibiting fishing with nets, weirs or seines in the waters of San Antonio creek.

A WASHINGTON dispatch says the impeachment articles against Belknap will probably be reported to the House this week.

THE bill of Lane of Oregon to provide for paying the expenses of the Modoc war will give California \$44,000 and Oregon \$70,000.

THE German Minister has given notice by the termination of the existing treaty of commerce between his government and China.

CHARLES H. BARTH, transportation clerk in the Quartermaster's Department, U. S. A., in this city, is discovered to be a defaulter to the extent of \$67,000.

A DIFFICULTY between the American and Mexican soldiers at Brownsville and Matamoros a few days ago ended in the death of one of the former and two of the latter.

A MEMBER of the House Foreign Affairs Committee is reported as saying that the testimony already heard in relation to the Emma mine had convinced them that it was the most gigantic fraud of the century.

THE Committee appointed to consider the question of checking the immigration of Chinese to California propose to make the movement general by having the people of the interior towns unite in an expression of opinion on the subject by the passage of resolutions. These expressions will be used to the best advantage in applying for relief in the halls of Congress, where legislation will be asked for.

A SELENIUM WORKER.—Since we adopted the Willcox & Gibbs sewing machine for stitching the backs this paper (about two months ago) it has worked like a charm. We have stitched over 80,000 copies without breaking the first needle! But a single thread is used and that is fed from the original spool. This saves frequent threading of the needle and does away with all winding of thread. We run the machine by steam power because that power is most convenient in our office. It is one of the very easiest running machines, as it is one of the simplest. A child can operate it. They are very perfectly manufactured, not likely to get out of repair, and will last a lifetime. The new machine has points of excellence over all others. We advise those who wish a low-priced machine to address the general agent, E. B. Cutler, 111 Post street, San Francisco.

The Cause of Hard Times.

Different theories of the cause of the hard times have been advanced by different persons. In the *Unitarian Review* for January and February John O. Kimball offers the following, which is interesting reading, at least:

"It is due simply to the introduction, during the last 25 years, of such an enormous amount of machinery. There is nothing in our modern civilization which is more wonderful, more significant, more a new thing under the sun, and destined to be more wide-reaching in its relations, than this use of machinery. A single pegging machine will turn out more boots and shoes now than a whole village of cobblers at work in their little creaking shops fifty years ago. The cloth woven in any of our large mill towns is probably equal to half of what all India used to produce by the slow and methods of the middle ages. Steam engines alone are doing a work which without them would give employment to every one of the multitudes of men and women who are now lying idle in our country. California a few years ago was groaning over the introduction of so much 'Chinese cheap labor,' and yet, at that very time, most inconsistently, was giving a welcome to mowers and reapers and mining apparatus which for cheapness and facility of use made even a Chinaman dear. And then, when it is seen how these muscles and nerves of iron and steel are employed in every department of industry, from carving into shape a shaft of iron weighing 20 tons, down to the finishing of a cambric needle, and from the sewing of a buttonhole to the sowing and reaping of whole States, who can wonder that the market is overstocked?"

"Of course this increase of facilities for doing work increased for a while the amount of work to be done. But such a process could not go on forever. There was a limit even to the number of stitches which could be put into a lady's dress, and to the amount of wheat which even an American family could make way with. And this point has at last been reached. The occurrence of our civil war, with its enormous destruction of property, and its withdrawal of energies into the battle field, put off the day; but the end of the war, and their return again into the pursuits of peace, soon filled up the gap, and brought us to the point where it was hardly possible to consume a half of what was being produced—the point, therefore, where business was obliged to stop."

J. H. CULVER, Secretary of the board of managers of the Mechanics' fair, has been commissioned to visit Philadelphia this year, and do all that is possible to add to the attractions of the fair this year by securing interesting exhibits from the East and Europe.

OF INTEREST TO

MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially machinery for mechanical ore concentration, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

PHILADELPHIA.

FOR SALE BY ALL THE LEADING JOBBERS.

Geo. M. Grant & Co., Agents. San Francisco.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you
sent to Baldwin & Tabor, Manchester, N. H. We ran it most
all day, and ground 60 bushels corn per hour. The mill you
sent us at Haverhill, Mass., for A. S. Hook, is doing wonder-
fully. It is grinding on an average 2,600 lbs. good meal per
hour, and has ground 2,800 lbs. in an hour. It is driven by an
engine with a 9-in. cylinder, and takes the place of a 30-in.
mill of another kind that, when doing its best and loading
the engine with all it could carry, only ground 1,500 lbs. per
hour. If there is a mill built that can beat that we would be
pleased to see it brought out."

(Continued from Page 214.)

Arizona.

GLOBE DISTRICT.—Cor. Arizona *Citizen*: Excitement has run high during the past week throughout this whole district, owing to the discovery made by John Alvane, on the northeast slope of the northwest peak of the Apache mountains, about six miles north of here. The vein struck in this discovery is looking very well as far as developed, and has been named the Richmond. Several arrivals from Silver City, Phoenix and Prescott, within a week, have increased our numbers here to 200, certainly, and the cry is still they come. The shaft of the Richmond is now down 37 feet, and the character of the formation improves daily and is very encouraging.

Idaho.

ROCKY BAR.—Cor. Idaho *Avalanche*, March 18: The Buffalo company have extended their lower tunnel across their Atlanta ledge, some 60 feet, and about two weeks ago they struck a fine pay streak near the south wall, which measures three feet 10 inches in width, and assays from \$75 to \$300 and over per ton. This streak is improving as they go west, and they are now getting out both ruby and brittle silver in abundance, which they are sacking for shipment. While at Red Warrior, the other day, I visited the Burnt Pilot mine, owned by Messrs. Hicks & Porter. They have labored diligently this winter, having sunk a shaft 50 feet on their vein, and then drifted east on it from the bottom of the shaft a distance of 30 feet. This drift will be extended 20 feet further, when they will commence stopping. By running about 50 feet further they will strike their ledge at a depth of 270 feet, and will then have open one of the best gold producing mines in the camp, and which is bound to yield them a handsome stake. There is nothing new to note in regard to other mining operations since my last report. The above are but instances of what can be accomplished here by energetic, hard working men. Any amount of mine can be got hold of by men who are not afraid to use their muscle; there is room here for all, if they will only come.

WOODWARD'S GARDENS embraces an Aqueduct, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

California Acclimatizing Society—Location of principal place of business, San Francisco, Cal.

Pancake Coal Mine.

A gentlemen just in from the Pancake company's coal mines, informs us that two stratas of coal have been struck in the new double shaft that the company have been for several months past engaged in sinking, which is now down to a depth of 225 feet. The first strata was struck at a depth of 190 feet, and is 15 inches in width. The second was struck at a depth of 200 feet, and is three and a half feet in width; in the deepest strata the coal is of a very superior quality. After going through the two stratas of coal a short distance a body of water was struck, which will require a little delay in putting in a pump, and will also incur the time and expense of getting a boiler of larger capacity than the one now in use. This, we understand, is to be done immediately. As soon as work can be resumed, proper levels will be run to extract the veins of coal that have recently been struck, and the sinking of the main shaft will also be continued to strike other stratas that are known to exist at a greater depth. Those at all familiar with the workings of this mine will remember that a large amount of work has been done that was impractical, but not entirely thrown away, as, while being done, several veins of coal were discovered and their courses ascertained. The present company being in possession of all these facts, concluded to sink a double shaft and put up extensive hoisting works, and located the new shaft with a view to cut the veins that had been developed by the old workings, which they have succeeded most admirably in doing. The recent strikes have fully developed a continuous series of coal veins, which will be largely worked during the coming summer. We are also informed that it is the intention of the company to erect extensive works at Enreka for the manufacture of coke, to be used by the numerous smelting furnaces at this place. There is little doubt but coke can be manufactured there cheaper than it can be freighted from the East, and allow the company a fair profit for their coal and its manufactures. It is now an established fact that we have extensive coal beds in White Pine county, which will prove quite as remunerative as any silver mines in the State. We congratulate the company on their new find.—*White Pine News.*

On the Ophir mine the excavations for the pumping machinery are rapidly nearing completion. The tar-house having been destroyed by fire a few days ago, it is being rebuilt on the east side of the railroad track, so as not to again endanger the main buildings. No fire will be used in the house after this, as the tar will be heated by steam, conveyed in pipes from the boilers. This is a vast improvement over the old style of heating the tar by a fire, and is well worth copying after by every mine on the line of the Comstock.

WATER TANKS of any capacity, made entirely by machinery. Material the best in use; construction not excelled. Attention, dispatch, satisfaction. Cost less than elsewhere.

WELLS, RUSSELL & CO.,
Mechanics' Mills, Cor. Mission & Fremont Streets

TOWNSEND, WYMAN & CO.,
Real Estate, Mines and Mineral Lands,
420 Library Street, Philadelphia.

Coal, Gold, Silver, Lead, Iron and Copper
Miners Bought and Sold.

Taxes Paid, Titles Examined, Mines Examined and Reports Made, Mining Companies Organized, Geological Reports Made, Surveys Made, Engineering Done, Assays Made.

Agents for MINING MACHINERY, ENGINES, Etc., and Attorneys for WERNI UNINFLAMMABLE and INDESTRUCTIBLE WOOD PRESERVER.

Consignments of Minerals Solicited for Centennial.

Mining Superintendent.

E. B. Smith, for nearly twenty years engaged in the direction of mines and mining enterprises, can be engaged to take charge of any legitimate mining enterprise. Mr. Smith thoroughly understands the "Sonora" process of chlorination and lixiviation, being the originator of the same, and the erection of all machinery and furnaces for the treatment of rebellious ores.
Office—439 Bush street, S. F.

MINING ENGINEER.

A Mining Engineer, with the best of best of references, thoroughly experienced in the opening and superintending of mines and mills, desires an engagement. Address, "MINING ENGINEER," MINING AND SCIENTIFIC PRESS Office, San Francisco.

Giant Powder.

Patented May 26, 1868.

THE ONLY SAFE BLASTING POWDER IN USE.

GIANT POWDER, NO. 1.

For hard and wet Rock, Iron, Copper, etc., and Submarine Blasting.

GIANT POWDER, NO. 2.

For medium and easy Rock, Limes, Marble, Sulphur, Coal, Pipe Clay and Gravel Bank Blasting, Wood, etc.

Its EXCLUSIVE use saves from 30 to 60 per cent. in expenses, besides doing the work in half the time required for black powder.

The only Blasting Powder used in Europe and the Eastern States.

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE
MOST THOROUGH TRIALS

Ever Had in the United States,
BETWEEN COMPETITORS

—OF—
Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

—FOR—
Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the best ever made in simplicity of construction, economical use of power, durability, and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim. Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

BEFORE PAINTING YOUR HOUSES

Send for Sample Card and Circular and Carefully Examine the

AVERILL CHEMICAL PAINT, MIXED READY FOR USE.

This Paint is prepared in liquid form, READY FOR THE BRUSH. It requires no addition of oil or spirits. It is composed of the best materials known to the trade—Pure Linseed Oil, Strictly Pure White Lead, Pure Zinc, and the finest of coloring matter for tinting. It is the BEST, CHEAPEST, MOST DURABLE AND BEAUTIFUL PAINT IN THE WORLD. Is just what is wanted by every farmer, mechanic and everybody who has a house, fence, barn, or wagon to paint. Requires no skilled labor, as any one can apply it who can handle a brush. It is put up in cans of any required size, from a quart to five gallons, and is sold by the GALLON. It gives a firm, elastic and brilliant glossy finish, and will neither crack, peel or wash off, like most paint in common use, but is proof against reinetorms and all action of the elements. Buildings painted with this paint five years ago look fresh and like new to-day and will need no more paint for years. Of no other paint can this be said and proved.

The Averill Chemical Paint Company supply a long-felt want. They not only furnish a Paint more lasting, handsomer, and at the same time cheaper than the best of others, but it is in a liquid form—white and all the fashionable and most exquisite shades—ready for the brush. So that farmers, in fact everybody, can be their own painter if necessary. Indeed, all the buildings upon which the Averill Chemical Paint has been applied, are marvels of beauty.—*Christian Union*.

We know of no subject of such importance to householders as that of a good, handsome, durable paint for their dwellings. Within the past few years we have watched the progress of the Averill Chemical Paint and have had frequent opportunities to test it fully. We think it just the article to supply the need, and give it our hearty endorsement.—*N. Y. Independent*.

From the Thousands of Testimonials sent us, we select the following, which we present for your careful consideration:

A PAINT FOR FARMERS.—Prof. J. B. Turner, Jacksonville, Ill., is a man of great practical knowledge and experience; hence, we attach a great deal of value to the following, from his pen, which we find in the *Prairie Farmer*:

"Some two years ago I sent for and got from a barrel to a barrel and a half of Averill Chemical Paint, of light dun color, which I thought would suit me well enough for all work—houses, doors, blinds, fences, bee-hives, wagons, tools and all. I put two coats upon my residence here, and run over three or four of my smaller farm houses on my farms. With what was left I painted my bee-hives, wagons, wheelbarrows, rollers, harrows, fences, etc., etc., and on all these buildings, implements, tools, gates, etc., the paint is as hard and glossy to-day, so far as I can see, as it was a month after it was put on, and holds fair to hold its own at least for five years to come, (if not ten of them,) better than ordinary white lead and oil does for even two years.

"I have watched it now for about two years with interest and care, and have never found a single spot where it peeled, cracked, or chalked off, as our other paints do. Others who have used this paint like it equally as well. But the point is, I can take one and the same keg and brush, and go over all my buildings, wagons and tools, with no needless waste of paint, brushes or time. It is quite as good for inside finish, as it leaves a coat that shines and washes like glass."—*Moore's Rural New Yorker*.

THE AVERILL PAINTS.—In reply to some inquiries of our readers, we would state that we have given these paints, prepared by the Averill Chemical Paint Company, a full trial, and they appear to possess all that is claimed for them; spreading easily, adhering well, drying soon, and imparting handsome shades of color to the surface covered. Farmers and others who do their own painting, may avail themselves of the convenience of purchasing these paints, of any desired shade, already mixed for use, at a very reasonable price.—*Cultivator and Country Gentleman*.

TO THE CALIFORNIA CHEMICAL PAINT CO: Gentlemen—In reply to your letter I have to state that for more than six years I have dealt in and used your paint. I have during that time carefully observed its application and use, and from practical knowledge can certify to its unrivalled excellence. During my six years' acquaintance with it, there has not come to my knowledge a single instance of failure in any case where it has been used. All to whom I have supplied it unite in commending it for its superior claims over all other paints now in use. The Averill Paint externally used, or, in other words, exposed to the action of the weather, neither rubs off nor changes color, as do other paints, and will retain its freshness and adhesive property for years. Pure lead and oil will in a short time become dry, and are easily rubbed off; the loss of oil leaves the lead in a dry, oxidized state. As a matter of economy the claims of the Averill Chemical Paint to popular appreciation and general use are beyond question. A house properly painted with it once will be better preserved, and present a neater appearance at the expiration of seven years, than it would if twice coated with lead and oil paints now in use. There can be no question, then, that to use it is both labor-saving and economical. So well assured and convinced am I of its established right to this distinction over all kinds, that had I fifty houses of my own to be painted, the "Averill" alone should be my choice and used.

Yours, very truly,
S. J. ALDEN, Druggist.

TO THE CALIFORNIA CHEMICAL PAINT CO: Gentlemen—In reply to your note of the 13th inst., I willingly state that the work done by you in painting the exterior of the North Hall or College of Letters is in every way satisfactory, and the appearance of the building since it was painted excites the favorable comment of all who have seen it. As I have had occasion to use the Averill Paint before, my experience has been such that I prefer it to any and all others when properly applied. I am very truly yours,
ROBT. E. C. STEARNS.

Allen's Fracture Bed.

We illustrate on this page a surgical bedstead, the invention of Oliver Allen, of Petaluma, which is constructed in such a manner as to be of great assistance to both the surgeon and the patient in cases of fractured limbs, and which has many new features to recommend it. We examined carefully last week one of these beds in the surgical ward at the City and County hospital, and although a detailed description of it may make it appear a complicated affair, a little study of its construction from the engraving presented will show that its general features are quite simple. Upon it fractures can be cured without shortening of

spite of our best efforts there always will be some shortening," and "if a case results in but half an inch shortening it is a good cure."

The "fracture bed" and its appliances compose an apparatus which is the result on the part of the inventor of an effort to make something durable, convenient and satisfactory to both patient and surgeon, and in which any forms of fracture in either limb or limbs of any length, a perfect tension may be kept up with little discomfort, a perfect dressing may be quickly effected, and in which after dressing require no removing of appliances, or the least disturbance of the fractured parts. These results are practically attained; in addition to which the surgeon cannot fail to feel perfectly secure and the patient comparatively comfortable. The apparatus is really simple and is adapted to many purposes by purely mechanical arrangement.

horizontal flange, and this flange is upholstered so that it will form a soft cushion.

A space is also left around the metal lining of the mattress, so that when the mattress is pressed down the upward projecting flange of the hole in the bed bottom will enter the space and allow the mattress to be compressed.

Underneath the bed are secured two transverse rails, *h h*, one on each side of the hole. The inner edges of these rails are grooved so as to receive the opposite flanges of a pan or chamber vessel, *I*, and allow the vessel to be moved along underneath the bed until directly under the hole. When the vessel is not in use an upholstered plug, *J*, for filling the hole is employed. This plug is long enough to be passed up into the hole from beneath the bed, *A*, and extend to the upper part of the mattress, *E*, and make an even surface. To the lower end of the plug is secured on a

be too short when the fracture heals.

In order to adjust the patient properly for the purpose of obtaining a correct extension the inventor uses a measuring bar, *S*, (Fig. 2), which is supported at each end by a standard, *T*, at the middle of each end of the bed, so that the bar, *S*, will pass longitudinally above the middle of the bed and the patient. The standards, *T*, are made of two parallel pieces of wood, between which the ends of the bar, *S*, are placed and adjusted to any desired height. A link, *u*, at the top of the standard, is then used to draw the two parts together to keep the bar in place. Upon the bar, *S*, is placed a transverse sliding bar, *V*, the arms of which project upon each side of the bar, *S*. A set screw serves to fix the transverse bar in place.

Upon each arm of this bar, *V*, is placed a downward projecting sliding finger, *W*, and these sliding fingers are connected with a slid-

ALLEN'S FRACTURE BED WITH APPLIANCES.

the limb, while the patient is kept comparatively comfortable and all his wants supplied without disturbing his position. A fractured leg or thigh, especially if it be compound, is surely a matter of too much importance to both surgeon and patient to submit it to packing in a hot fracture box, or lashing it to a strip of board with the padding necessary to make it endurable, and which, for the purpose of inspection, requires such manipulation that the fractured bone will be jostled about, and any efforts at reparation thus interfered with. The ability to examine any part of the injured limb at any time without its disturbance, and without interfering with the extension, is certainly very important, and perfect control of the positions of the foot is equally desirable, both of which are secured in this appliance.

It is certain, moreover, that the surgeon must have both limbs extended alike, and have a more accurate method of measuring than the old one before he can be certain he is not deceiving himself in measurement. It is stated that the difference in length between a limb in its extended and unextended condition is about half an inch—sometimes more, sometimes less—as any one can easily convince himself. It is at least probable that this error in measurement, and the heretofore imperfect manner of measurement, are the two principal reasons of surgical authorities teaching that "in

The bedstead itself is provided with all the necessary appliances and conveniences for reducing and curing fractures of those bones in the human anatomy which require extension in order to keep the fractured parts in apposition while union is taking place.

In the engraving, *A* represents the bed bottom, which the inventor makes solid, as a board bottom is best adapted to the various devices which are to be attached to it. The bed frame or bottom is supported on legs which are arranged so as to be removed if desirable. The removable head board is secured to one end of the bed by screws and is supported by side brackets. In order to provide for the evolutions of the patient, a hole is made through the bed bottom at the proper place and a corresponding hole through the mattress and sheet, as shown in the sectional cut. The hole is lined with metal, and the lining projects upward above the level of the bed bottom, so as to form an upward projecting flange which entirely surrounds the hole. The hole in the mattress is also lined with sheet metal, and this lining projects downward on the under side of the mattress, so as to pass inside of the lining of the hole in the bed bottom, thus forming a perfectly water tight passage through the mattress and the bed bottom. The metal lining of the hole in the mattress is screwed to the top of the mattress around the edge of the hole by a

strong screw rod a horizontal bar, *k*, which can be turned after the plug is introduced so as to lock the opposite ends into the grooves in the rails, *h h*, and thus secure the plug in place. By turning the screw rod shown the plug can be properly regulated in case any depression occurs from the weight of the patient's body.

To the foot of the bed is secured by means of screws two parallel boxes, *L L*, so that their rear ends will project beyond the foot of the bed. Each of these boxes has a sliding top, *m*, and a roller, *n*, is placed across the rear end of each, its journals bearing in the opposite sides of the box. A strap, *o*, has one end secured to the rear end of each sliding cover and passes over the roller, while a tin bucket, *P*, is attached to a spring balance on the opposite or hanging end of the strap. Upon each sliding top, *m*, are placed two studs, *r r*, one directly in advance of the other. For convenience a roller is placed on each stud, the roller of the front stud, *r*, being smaller than the one in the rear stud, *r*, for the purpose hereinafter explained.

When the patient is placed upon the bed the first thing to do is to place him or her in the proper position, and by extending the well limb, determine accurately the amount of extension to be applied to the fractured one. This is necessary, as hereafter explained, otherwise the fractured limb is liable to

ing block, *X*, by links, *Y*, so that by moving the block, *X*, back or forth along the bar, the fingers, *W*, will be moved toward or from each other along the arms of the bar, *S*; a sliding finger, *Z*, is also placed upon the bar, *S*, at the head of the bed. When the patient is placed in the bed, the finger, *Z*, is moved against the top of his head, and secured in place by a set screw. The transverse sliding bar, *V*, is then moved opposite his shoulders, and his body adjusted until the fingers, *W*, press equally upon both shoulders. The same operation is repeated with the hips, thus bringing the body of the patient in a perfectly straight line.

At the foot of the bed, bars, *b b*, are arranged to slide horizontally in a socket formed between two of the boxes, *L L*, one upon each side of the bar, *T*. To the outer end of these sliding bars is secured, by a bolt, an upright bar, *d*, the upper end of which is curved over toward the middle of the bed, so as to provide a fender, which will prevent the weight of the bed clothes from falling upon the feet of the patient. Near the lower end of this bar is a horizontal arm, *1*, which projects toward the middle of the bed, and upon the extremity of this arm is formed a heel pad, *2*, as shown. A sliding arm, *3*, is arranged to move up and down along the bar, *d*, between the arm, *1*, and the upper curved

(Continued on Page 233.)

CORRESPONDENCE.

Botanical Excursions.

[By J. G. LEMMON.]

No. 1.—Pyramid Lake and Humboldt Desert. (Concluded.)

Gathering a variety of strange plants amidst the sage brush and scoria of Pyramid lake valley, we prepared for the further journey in search of exceeding horrors by stopping at the house of Dr. Wood, the only white inhabitant of the north shore, to re-organize, obtain supplies of food, and get directions and instructions where to find and how to prepare for

Humboldt Desert.

Northeastward of Pyramid lake, separated only by a low ridge, and stretching away to the Humboldt mountains, is a great desolate plain, in the burning center of which is seen the work of evaporation so offensively illustrated in Pyramid valley carried to completion. The result is, a white, level, hard, deeply cracked bed of residual matter, extending 40 miles in a nearly circular shape. This is the sink of the Humboldt. The waters of this largest of the great basin rivers—increased ten-fold in winter—overcome the less evaporation of that season and flood the whole desert, moistening the conglomerate elements of the bed, to reek with pungent, stifling gases the long summer after. No animate objects are seen in all its bordering plain for hundreds of miles, and few are found save only myriads of large black mosquitos that rise out of the low bushes, and without a note of warning attack the intruder as if they expected but one meal in all their lives. This desert—a type of the beds of the evaporated lakes of the great basin—cannot be appreciated by merely gliding along its borders in the rail cars of the C. P., stopping only at the oases. One must be obliged to stagger blindly through the glare day after day, and camp upon its steaming floor at night.

We took our fill of Humboldt desert in two days and one night. That night was spent out on the rank smelling floor to rid ourselves of the mosquitos. Seven million four thousand and ninety-eight (as Mark Twain would say), followed us out, and not until after a battle of two hours with bushes did we trim off their bills, so as to be allowed to rest—but for a season only. The poor ponies, tethered to bushes on the shore, suffered such pain from the poison, evinced by constant neighing and rearing, then rolling in the alkali, that in mercy we led them out, tied them to our wagon wheels, and fought 9,473,608 solid feet of mosquitos, until becoming exhausted, we crowded into the wagon, dropped the curtains, crept under five pairs of blankets, with our boots on and a hake kettle over our heads.

The only way we could botanize the plain next day was for me to arm one band with a bush, and continually whip my face, with the other hand grasp blindly for flowers, while Prof. Case stood over me with a wisp of bushes in each hand, with which he lashed alternately my shoulders and his own. We thus secured a number of rare prizes, among them a fifth new *Astragalus*, which properly bears the name of *Astragalus Casei*,—Gray.

The White Monuments.

Through the glare and exhalations we gazed with shaded eyes out over the shimmering floor as over a sheet of iron raised to white heat. We knew that the old emigrant route crossed this terrible desert near, and from an eminence we could detect far in the distance and stretching across the waste that broad belt of whited skeletons that commemorate the toil, exposure and death of so many animals and men in the early pioneer days. Let the California poet describe the appalling spectacle. I cannot.

Who journeys o'er the desert now
Where ebbs engulfed the Humboldt river,
Arrested in its sudden flow
Yet pouring in that sink forever,

Who journeys o'er that desert now
Shall see strange sights and ghastly,
For he shall trace afar, slow,
Across this waste extended vasty,

A zone of bones that bleaching lie
Where fell the wearied host o'er-driven,
And upward cast its dying eye
As if in dumb appeal to heaven.

For lengthening miles on miles they lie—
These sad memorials, grim and hoary,
And every whitening heap we spy
Doth tell some way-worn pilgrim's story.

Hard by each skeleton there stand
The wheels that drew, or warped, or shrunken,
And in the drifted, yielding sand
The yoke or rusted chain lies sunken.

Nor marvel we if yonder peers,
From out some scooped-out grave and shallow,
A human head, which fleshless leers
With look that doth the place unallow.

Each annual pilgrimage hath strewn
These monuments, unnamed, undated,
Till now, were bones but piled on bones
And thousand wrecks but congregated,

A pyramid would rise as vast
As one of those old tombs, Egyptian,
To tell of toil more great—long past,
And death—without their dim inscription!

Return to Pyramid Lake.

Returning by the same route to Pyramid lake which looked quite beautiful now after

the desert, Prof. Case amused himself with shooting pelicans from the rocks along the beach, while I drove along the dreary road, unenlivened now by the novelty of its floor, once seen. By practice my vision at a certain range has grown so keen that four rods off I can detect plants two inches high and distinguish their characters, but I see nothing else. A hare or sage hen I seldom note, much less a gopher or owl. Perhaps this is why I have not seen a grizzly bear in all my travels. Case declares, however, that it is because of my inveterate whistling or singing, enough, he says, to frighten a grizzly a half mile away.

On this monotonous home trip along the shore of Pyramid lake for 30 miles, I only found one plant not seen before, but that proved to be a very interesting new species of Dr. Gray's new genus, *Glossopetalon Nevadaense*. It is a spinescent shrub of bright green hue and growing in one ravine only near the water's edge.

The Boat Ride, and What Came of it.

Going into camp, as we thought, near the south end of the lake, one day at an early hour, seeing a skiff moored in a lagoon and being out of provisions the Professor proposed that we improvise a sail for the skiff and go over to the reservation—seemingly only a few miles—for supplies. I readily consented and picketing the ponies with long ropes on a patch of salt grass with the lagoon accessible, I assisted in handling equipments for a day's botanizing and hunting into the skiff, upon which Case had rigged a sail made of a blanket spread by a long stick lashed with haling rope to an oar for a mast. Another stick distending the lower corners of the square sail the Professor held in his hands, while with the other oar I guided the craft. Gayly we sped over the dark waves, driven by a fine breeze nearly astern, past Pelican rock, (pshaw, what a smell!) past promontory and cove, islet and sand bar, the wind freshening at sundown to a stiff breeze, driving our little skiff before the white capped waves, faster and faster. Our black ponies and white covered wagon disappear, but the supposed patch of willows seems not a rod nearer. Passing at length a gorge in the mountain rim a gust of wind issuing from it steered our skiff around and drove us towards the roaring sea. A second gust wrenched the sail from Case's grasp and almost capsize the skiff. Screaming with delight he recovered the sail, while with difficulty I brought the boat to the wind. I began to express fear of danger, which Case scouted as groundless, and on again we flew before the gale. Time after time the boat was nearly capsized and the sail yard got away from Case. Thoroughly alarmed I appealed to him to lower the sail. "I have weathered worse squalls than this," he replied cheerily, but his voice was nearly lost in the roar of the sea, its face now too furiously swept for waves, appearing a level sheet of foam. "Case!" I cried at last, "I would as leave go down here as anywhere, and with you as anyone, but think of the trouble it would give to learn our fate. Think of the Odd Fellows. Think of our mothers!" He obeyed instantly. Wrenching out the mast he threw the sail overboard, and not a moment too soon. A squall laid our skiff on her side and drove the foam sheer across her length, but strangely enough we shipped but little water and our craft instantly righted. "You're right, Lemmon," said the sailor with emotion, as he joined his strength with mine, now at the oars to keep the skiff afloat, and head her shoreward. Only by the exercise of our utmost strength could we hold our position in the wind's eye. Squall after squall struck our little skiff and tossed it like a cockle shell to leeward. A half hour passed. Not a rod gained. We studied precision of stroke, pressed our oars deep into the brine and pulled for dear life. An hour. The shore but a few rods off at the first, seemed a few feet nearer! "Take courage," cried Case, "we are gaining." Two hours of the most desperate rowing ever I saw, and the gallant Case, jumping into the breakers, seized the skiff and drew it to land!

Rest followed; rest the most refreshing and fullest enjoyed as we lay for five minutes outstretched upon the sand. Then came resuscitation and the taking of observations for whereabouts and condition. O, so thirsty, so hungry, so tired! Saved helply from a watery grave, but on a bleak shore, our wagon and the lagoon of drinkable water an unknown distance away, darkness closing down and the watch showing 8.30 by the titill match. We resolved that we must pack ourselves with our things and find the wagon where was water, three little mourning doves the Professor had lagged during the day and a roll of blankets. Dividing our things into two parcels we found that in our thoughtlessness, nearly all our wagon load had been put into that skiff. An enumeration of the heavy articles, guns, equipments, game bags, flower presses, etc., would require a long paragraph. Staggering through the yielding sand, tangled often to falling by the low bushes, we toiled onward. Every few rods we were obliged to halt and take a rest. Night deepened to intense darkness ere the glad but husky voice of Case far in the advance announced the white wagon in sight. O, what sweet water! Never was tastier meat than that raw morning dove! never softer feathers than that wagon box!

Well, I have done some terrible marbling in my day, have been driven by overpowering columns to wade to my knees night after night through the red clay mud of Georgia, and I have suffered for six months the starvation fare of Andersonville. But I was young then. It seems to me now that the row for life on Pyra-

mid lake and the search for water and food that night was the very climax of toil and pain!

But you, dear reader, end we, have had enough of Pyramid lake and Humboldt desert. Brighter voices of a kinder clime invite description, and time is short. Hastening the next day over the worst of roads, so rough that I had to hold the wagon upright with a long guy rope, upon which I pulled with all my strength as I walked along the bluff above, to the agency 28 miles, where we obtained a square meal, rested a half day, learned much concerning the Piutes—especially their superstitions and names of desert plants—visited the curious volcanic, toad-stool-like columns in the vicinity, then hastened homeward via Wadsworth, Reno and Crystal peak to Sierra Valley, a round trip of 420 miles in 15 days, our wagon piled to the peak with bales of flowers, our faces brown as Indians, our eyes blood shot, but our minds indelibly impressed with very many exceedingly pleasant memories and one dark, startling, horrible night-mare—the boat ride on Pyramid lake!

Placer County Mines.

EDITORS PRESS:—Mining matters are very quiet here just now, several of the larger mines not being worked, and only one small four-stamp mill running on custom work. The Crater mine, belonging to the St. Patrick company, continues to show rock fully equal to its average, taken at present from the 312-foot level in shaft No. 1. This shaft has a depth now of over 500 feet on the incline. A 12-horse power engine raises easily all the rock the mill can crush, and could supply three times the number of stamps. Another engine of 20-horse power operates a five inch and a six inch pump. The pumps have five feet lift and a very low rate of speed keeps out all the water. Shafts Nos. 2 and 3 are not worked at present. A 15-stamp mill, operated by a 40-horse power engine, has been kept going all the winter, notwithstanding the difficulty of getting wood hauled, until March 1st, when the roads becoming utterly impassable for the wood wagons, operations ceased. Without more storms the mill will soon again be at work.

Bellevue and Green mines are not working, but the former is about to start under very favorable auspices.

The Kirkland company are working one mine light handed, and have recently bonded the Good Friday, which is now being prepared for active operations by straightening the shaft and retrimming some unsafe places. Some specimen rock from this mine exhibits a richness almost beyond belief.

A number of small claims are being worked with average success.

Near Newcastle, one mine, that of A. H. Sohnael, is actively worked. He is sole owner of this mine, and has been operating with more or less success for 12 years; but having started without capital aid development and improvements have been on the actual product of the rock. In reaching the present depth of 230 feet, six drifts have been made, but the rock is now being taken from the lowest level. At the 150-foot level the vein was 18 inches, and the present depth is four feet. The hoisting is done with a 25-horse power engine, which also raises in buckets all the water. There being nothing but surface water, no pumps are needed. Twelve teams are employed in the mine, and a Coe steam drill is now being put in. In the mill, 20 stamps are at work now, and 10 more are about to be added, worked by a 50 horse power engine. Everything here is solidly built upon heavy rock foundations, permitting no jar or vibration. There is a very marked equality in the yield of this mine, having preserved its average of about \$8 for years past.

Near Colfax the Rising Sun continues its steady work. Their ledge is almost perpendicular, and the shaft is now down 600 feet and ore being taken from this level. At the same time they are sinking for a 700-foot level. The 200-foot level has been worked 800 feet, and the east drift shows no signs of giving out. The shaft is partitioned, and two tubs used in hoisting, which is done with a 20-horse power engine. Another engine of same power works the two eight inch pumps, which readily keep out the water. Their works are arranged very conveniently, the mill being alongside of and under the same roof with the hoisting works, allowing one engine man to attend to the three engines. The rock is represented to average \$28, and since 1867 the mine has yielded \$350,000. The prospects now are improving, being decidedly better than two years ago.

Opbir, Plerce Co., March 30th.

SALES OF MINING PROPERTY.—We learned yesterday that one of the mines of Pennsylvania district, owned by Messrs. Sultan, Carlow and McDougall, had been sold to Mr. Higbee, of Oakland, California, for the sum of \$14,000. The money is payable on the 10th of April. Mr. Higbee, has also purchased the Green Monster, another mine in Long valley, both mines comprising 2,200 feet, for which he agreed to pay the sum of \$4 per foot. The contract of sale also provides for a mill, to be erected by the first day of October, 1876. The districts surrounding Pioche are looming up, and, as they can get supplies no nearer than Pioche, of course they will aid it.—*Pioche Record*.

Liability of Stockholders.

The following bill, having been passed by the Legislature and signed by the Governor, is now a law, and every one interested in incorporated companies should read it carefully:

An act to amend section 322 of the Political Code. Each stockholder of a corporation is individually and personally liable for such proportion of its debts and liabilities as the amount of stock or shares owned by him bears to the whole of the subscribed capital stock or shares of the corporation, and for a like proportion only of each debt or claim against the corporation. Any creditor of the corporation may institute joint or several actions against any of its stockholders for the proportion of his claim, payable by each, and in such action the court must ascertain the proportion of the claim or debt for which each defendant is liable, and a several judgment must be rendered against each, in conformity therewith. If any stockholder pays his proportion of any debt due from the corporation, incurred while he was such stockholder, he is relieved from any further personal liability for such debt; and if an action has been brought against him, upon such debt, it shall be dismissed, as to him, upon his paying the costs, or such proportion thereof as may be properly chargeable against him. The liability of each stockholder is determined by the amount of stock or shares owned by him at the time the debt or liability was incurred; and such liability is not released by any subsequent transfer of stock. The term "stockholder," as used in this section, shall apply not only to such persons as appear by the books of the corporation to be such, but, also, to every equitable owner of stock, although the same appear on the books in the name of another, and also to every person who has advanced the installments or purchase money of stock in the name of a minor, so long as the latter remains a minor; and also, to every guardian or other trustee who voluntarily invests any trust funds in the stock. Trust funds in the hands of a guardian or trustee shall not be liable under the provisions of this section by reason of any such investment, nor shall the person for whose benefit the investment is made be responsible in respect to the stock, until he becomes competent and able to control the same; but the responsibility of the guardian or trustee making the investment shall continue until that period. Stock held as collateral security, or by a trustee or in any other representative capacity, does not make the holder thereof a stockholder, within the meaning of this section, except in the cases above mentioned, so as to charge him with any proportion of the debts or liabilities of the corporation; but the pledgor, or person, or estate represented, is to be deemed the stockholder as respects such liability. In corporations having no capital stock, each member is individually and personally liable for his proportion of its debts and liabilities, and similar actions may be brought against him, either alone or jointly with other members, to enforce such liability as by this action may be brought against one or more stockholders, and similar judgments may be rendered. The liability of each stockholder of a corporation formed under the laws of any other State or Territory of the United States, or of any foreign country, and doing business within this State, shall be the same as the liability of a stockholder of a corporation created under the constitution and laws of this State.

Address by the Centennial Committee.

To the People of San Francisco:—Your Centennial Committee hereby calls your attention to the fact that the Legislature has declined to make any appropriation in the premises. This refusal, humiliating as it is to our State pride, compels us to action, as individuals. The world-wide reputation of Californians as a rich and liberal people, has certified in advance that the Pacific coast shall be properly represented at our 100th anniversary. We should feel, and all men would say that we had certainly fallen from our high estate, and were untrue to ourselves, if, in that hour of our national pride, we have done no part in the work—have no representation of our fabled wealth and productions—and copy not a conspicuous part in the grand display.

Nature has been bountiful to us of her treasures, and it is peculiarly fitting that the Golden State should be creditably represented at this national festival of our country's arts and products. Indeed, a neglect to so appear would be inexcusable, and a reproach to the people.

Our sister States, with much less of prosperity than has blessed us, and with no greater cause for exultation, have secured proper representation and ornamental buildings at the exposition, and expect to meet us there.

It cannot be that our National or State pride is less than theirs. To take our proper place at the Centennial exposition, it is necessary for our citizens to act liberally and with promptness.

We, therefore, urgently request that when our sub-committees, duly authorized, shall call upon you for that purpose, you will subscribe in such manner as to secure for yourselves and our State a respectable showing before the world, and which will maintain our historic fame for abundance, large-heartedness, public spirit and pride of country.

WM. S. O'BRIEN, President.

Committee: Geo. S. Dodge, J. B. Frisbie, J. P. Jackson, A. C. Bradford, F. MacCrellish, W. C. Burnett, Wm. H. Martin, Josiah Belden.

MECHANICAL PROGRESS

The Use of Steel in Boilers and in Locomotive Fire Boxes.

According to London *Engineering*, steel is coming into very general use in England for stationary boilers and locomotive fire boxes. That authority states that thousands of tons of steel boiler plates are now being turned out in Bolton, Barrow, Sheffield and elsewhere in England. Messrs. Hicks, Hargreaves & Co., of Bolton, alone have turned out considerably over 3,000 tons of steel boilers for stationary purposes, and they now never make iron boilers unless specially ordered to do so. Messrs. Platt Bros. have for a long time used nothing but steel for the boilers at their enormous establishments, and some of these steel boilers have been over a dozen years' service. Messrs. D. Adamson & Co., and other well-known makers too, have turned out scores of steel boilers for use at mills, etc., and Mr. Adamson has for a long time made it a practice to construct the furnace ends of the flues of Lancashire boilers of steel, even when the rest of the boiler is of iron. Steel boilers are also in use at sea, but as yet this material has not been so extensively employed for marine as for stationary purposes.

Mr. Webb is also introducing steel boilers on the London and Northwestern railway. This application of the steel boiler has been approached very cautiously and carefully, tests have been adopted to secure uniformity in the quality of the plates used, and it is certain that by maintaining this system of testing and by the proper treatment of the plates during their manufacture into boilers, Mr. Webb has been able to secure most highly satisfactory results. Before the nature of the material was properly understood, Mr. Webb, and Mr. Ramsbottom before him, met with failures, but these failures were regarded not as reasons for giving up a valuable material, but as lessons teaching how it should be used, and hence the present success.

Steel Fire Boxes.

On the London and Northwestern the experience as regards steel fire boxes has not as yet been anything like as extensive as that of steel boiler shells, nor has it on the whole been so satisfactory; but the knowledge gained has not been thrown away, and according to *Engineering*, Mr. Webb may now be fairly credited with having made a success of steel fire boxes as well as steel boilers.

The fire box plates used at Crewe are, after being rolled, dipped while hot into cold water, and are then re-heated and again dipped, this treatment being repeated four times. This mode of treating fire box plates—a mode which has also been resorted to in the United States—has remarkable effect in toughening the plate, while it also weeds out any which are unsuitable. Among the things taught by experience, both in Europe and in America, is the fact that it is desirable to protect the riveted joints of steel fire boxes as much as possible from the action of the fire, and it was this belief which led Mr. Webb to design the system of fire box construction which he now uses, a system by which the corner joints are avoided, while the tube plate is flanged outwards towards the barrel.

Reverberatory Furnace and Cupola Iron.

Iron melted in a reverberatory furnace is stronger than when the melting has taken place in a cupola. The reverberatory iron has a strength of 5,000 pounds to the square inch greater than when melted in a cupola. The minimum of all good foundry iron should show a strength of 25,000 pounds to the square inch. —*Mines, Metals and Arts*.

The maximum should show a strength of over 32,000—approaching 33,000 pounds to the square inch. Between castings made from a reverberatory furnace (air furnace) and from a cupola. The above is about the mean of the relative strength of the two. In cast iron, as in most other materials, strength and hardness are to some extent opposite. When your castings are hard they lack strength, and when strong they lack in hardness. To combine the two, a coal blast charcoal iron cast from a reverberatory furnace presents in the fracture or finished face of the casting a mottled appearance, and this, to the educated eye, shows its character. —*Am. Manufacturer*.

BOILER TUBE STOPPER.—To insure speedy repair in case of collapsed boiler tubes, a new stopper, or self-acting plug, has been introduced and tried with success. It consists of two iron pistons, slightly less in diameter than the diameter of the tube to be closed, and joined together by a wrought iron rod 46 centimeters (about 18 inches) long. On the face of each piston is cut a square ring or groove 13 millimeters (about half an inch) wide. A rubber ring is fitted in each groove, thus making a loose packing for the piston. Small holes are also bored through the inner face of each piston, and just under the rubber rings. In use, the stopper is pushed into the tube till one piston passes the fractured place. On raising the steam, the water enters behind each piston through the break, and pressing on the inner side of the rubber rings, through the holes beneath them, expands them till they plug the tube in both directions. —*Scribner*.

Small Steam Engines.

The idea of making small steam engines in iron frames, so that they may be screwed to an upright wall, like a picture or clock, is being carried out. By this device they are placed in a secure and convenient position, are easy of access, and economical of floor space.

A correspondent of the *Scientific American* speaks as follows of what a small steam engine with a "home made" boiler may do for a farmer's purposes:

As many of your readers are interested in the performance of small engines, I will tell you what we have accomplished with one, diameter of cylinder of which is three inches, and length of stroke five and one-fourth inches. I can only give you the amount of work done, for we have neither steam gauge nor water glass. On February 2d we threshed 239 bushels of oats inside of five and one-quarter hours. The threshing was 120 feet from the engine, and was driven by a one-half inch seagrass rope from engine to idler, thence by three inch belt to threshing. The snow drifted on the engine so that it was nearly covered; the parts that were hot, however, kept the snow thawed.

The boiler is of our own design, built entirely of one inch gas pipe, and has about 50 feet of heating surface. I have taken your paper for years, but I have never seen any design at all like this one. It works to a charm, does not leak a drop, and will stand immense pressure. It holds out three pails of water, and is as easily managed as any 36 or 40 horse shell boiler; and I have had some experience with such sizes. We have designed a pump expressly for this boiler, and I will venture to say it cannot be beaten for one holding so small a quantity of water. The amount of fuel used in threshing the grain above mentioned was four and one-half cords of old rails, cut to two feet lengths. The engine made about 300 revolutions per minute, working steam at full stroke. I can give you no better data, but I think the results are hard to beat. We are farmers and not machinists, but we have constructed the entire engine and boiler.

The above communication is from Mr. L. Cooper, of Cortlandville, N. Y. The very general call given by the newspaper press, about a year and a half or two years since, seems to have produced a large crop of small engines for various purposes, which will ere long be so far perfected as to prove a great advantage in almost every department of small industry.

The New Grinding Process.

The new process for grinding grain, recently introduced in New York, whereby the grain is beaten into flour instead of being reduced by a grinding process, is attracting considerable attention. The process is similar to that exhibited in this State, a few years since, for grinding quartz. The machine used has an external appearance like a fan blower. Inside iron disks or fans revolve with great speed—from 1,700 to 2,000 revolutions per minute. The wheat is, according to the *N. Y. Bulletin*, fed to these receptacles the same as in an ordinary mill, and goes through a similar holting and purifying process, and the flour comes out in a perfectly cool condition. At an exhibition given not long ago, 100 barrels of flour were produced from 450 bushels of wheat, a great saving of wheat as compared with the old system. It is claimed that one machine will do the work of 18 runs of stones, and with 25 per cent. less power, the capacity being estimated at 800 barrels of flour per day. It is said that millers who have witnessed the operation seem generally willing to admit that it would accomplish all claimed for it.

The paper from which we quote remarks that the machine may also be applied to the reduction of hard rock, quartz, etc. The experiments in that direction made in this State do not warrant the latter statement, as we believe they were not such as to warrant its practical application at any quartz mill on the Pacific coast. The beaters and walls of the machine could not stand the great friction attendant upon the reduction of rock. There is, of course, much less friction in reducing wheat to flour by this process, and the heating of the flour, so difficult to be avoided in the use of stones, will never trouble the miller who uses these heating machines.

A New System of Railway Signaling.

The Paris correspondent of the London *Times* says: The French Minister of Public Works has just addressed a circular to the railway companies, calling their attention to an apparatus designed to prevent the terrible accidents resulting from the inefficiency of danger signals. The results communicated to the companies, by the circular may be considered conclusive, and seem destined to make up for the inadequacy of optical signals, which are naturally thwarted by fog or by a sharp curve, an inconvenience which it has been attempted to remedy by fog signals.

In England a mechanical contrivance has been devised, putting in motion a rod which, being struck by the engine, produces a whistle; but experience has proved that this device is not infallible. The system indorsed by the Minister of Public Works seems, on the other hand, to meet every objection. It can be placed at any distance, as it acts simply by flying down a wire. The board which indicates danger in moving excites an electric current which leads to an apparatus placed in contact with the locomotive, and which produces a

loud whistle. As soon as the indicator no longer represents danger the current is interrupted, and the locomotive may come in contact with the apparatus without causing a whistle. These experiments have been made during snow, and have invariably succeeded, the warning being given at a sufficient distance to allow of a train at full speed being pulled up in time.

SCIENTIFIC PROGRESS.

Scientific Weather Predictions.

The telegraph of Wednesday last (March 29th) states that it was predicted a day or two previously that a very severe rain storm was approaching New York city, and that it reached the city as predicted, and at the date of the telegram "was raging violently." The wind was blowing a gale and the rain falling heavily. The indications were that the storm would continue through the night. The Signal Office reported that the storm had reached Indianapolis that day from the West, and was also raging at Pittsburgh, Nashville, Louisville and Cincinnati. It was first noticed on the 26th inst. (three days before) at Fort Gibson, Indian Territory, and had traveled east. There had been a great deal of snow all along the northern edge of its track, and on the southern edge a bitter cold snap was following in the wake of the storm.

The fact that storms may thus be predicted with a great degree of accuracy is now pretty generally conceded, and the utility of the Signal Service is beyond question. The chief officer of the Signal Service reports that 87 per cent. of the predictions made during the past year were verified by the results. The Bureau has arranged the weather programmes for the country for the past five years, and the chief officer feels bold to assume that its reputation as a useful institution is established.

SEEDS GERMINATING IN ICE.—INTERESTING SCIENTIFIC EXPERIMENT.—Having observed that seeds of *Acer platanoides* and *Triticum*, which happened to have come into an ice cellar with some blocks of ice, had germinated between these, M. Ulth was led to experiment on this subject. He placed seeds of various species in grooves made in ice blocks (inclosed in cases), over which he laid plates of ice, and kept the whole in an ice cellar. Other similar seeds were sown in earth surrounded by ice. The cases were placed in January, and observed in March and May. A number of seeds germinated, and those of *Cruciferae* and *Gramineae* seemed to do so with special facility. Those in ice and those in earth seemed to germinate pretty equally. The roots penetrated into the ice (in the former case), and an interesting question arose as to how this occurred. M. Ulth considers that the process was facilitated by the heat liberated in growth of the root, melting the ice. M. Sachs thinks that the ice (in the original case, which suggests these experiments) being surrounded by warmer bodies, these may have heated the roots by radiation; but M. Ulth points out that in his experiments the ice was too thick for this, and if such a cause had operated, other bodies frozen in the ice, such as straw and wood chips, would have got heated and sunk in the ice, which was not the case. —*Boston Journal of Chemistry*.

ANIMALS CAN ABSORB ATMOSPHERIC NITROGEN. The nitrogen of the atmosphere has generally, heretofore, been thought to have no other useful purpose in the economy of nature than to act as a mere diluent of oxygen and carbonic acid. Recently, however, Prof. Ville has doubted this assumption, and proved, by direct experiments, that the leguminous plants can absorb nitrogen directly from the atmosphere, while only the graminifolious plants need nitrogen in the soil, in the form of nitrate or ammonia. And now M. Charbonnier, a Berlin scientist, comes forward with a treatise in which he assumes to prove that animals may also derive nourishment direct from the air. He shows that emaciated human beings can live for long periods without food, maintaining that the nitrogen from the air which finds its way into the circulation through the process of breathing is alone sufficient to sustain life. The Belgian society of medicine regards this theory of importance enough to direct the publication of the memoir in its printed transactions.

A WORTHY SON OF A SCIENTIST.—Mr. Alexander Agassiz has recently been elected to his father's place in the three principal zoological and natural history societies of Europe, in each of which the number of foreign honorary members is limited. He has been also the first to receive the grand honorary Walker prize of the Boston Society of Natural History, which is given only once in five years for the most important publication on natural history of the United States during the previous period of five years.

NEW PROPERTY OF GLYCERINE.—R. Godeffroy, on examining a chemically pure glycerine from the Apollo Japan works, in Vienna, found that when heated to 150 deg. it took fire, and burned with a steady, blue, non-luminous flame, without diffusing any odor or leaving a residue. The glycerine had the specific gravity of 1.2609. This property enables glycerine of lower specific gravity to be burned by means of a lamp wick.

A New Fossil Reptile.

At a late meeting of the London geological society, Prof. Owen read a very interesting and important paper on the "Evidence of a Carnivorous Reptile About the Size of a Lion." A small portion only of the reptile had been found—merely a portion of the jaws and the left humerus. The upper jaws displayed a pair of carnivorous canine teeth. The fossil was from a supposed triassic formation in South Africa, a locality which has already given to science a large number of most remarkable and characteristic specimens of the reptilian type.

The Professor discussed at some length the remarkable resemblances presented by these early reptiles, in some parts of their organization, to mammals, and referred to the broad question opened out by their consideration. He inquired whether the transference of structures from the reptile to the mammalian type has been a seeming one, due to accidental coincidence in species independently created, or whether it was real, consequent on the inheritance of species by secondary law. The lost reptilian structures dealt with in the paper are now manifested by quadrupeds with a higher condition of cerebral, oculatory, respiratory and tegmentary systems, the acquisition of which, the author thought, is not intelligible on either the Lamarckian or Darwinian hypothesis.

He discussed, somewhat in detail, the character of this new fossil, and intimated the probability that there exists a whole group of reptile genera in the lacustrine deposits of South Africa, all caravivorous, presenting more or less mammalian analogies, and for which he proposes to form a distinct order, under the name of *Theriodontia*.

The President remarked that Prof. Owen's paper was a most important and suggestive one, especially as regarded the views advanced respecting the connection between these old carnivorous reptiles and the mammalian carnivores.

Prof. Saley alluded to the extraordinary characteristics presented by the creature described by Prof. Owen; remarked that the present representatives of the *reptilia* are the chelonians, crocodiles, lacertilians and ophidians. He considered that there could be no doubt as to the connection between reptiles and mammals, and that Prof. Huxley was wrong in his views as to the relationship between birds and reptiles. Every mammalian type has a reptilian brain in its earliest stages. The suggestion of the formation of a new order seemed to him to be founded upon certain points which could not be regarded as absolutely proved.

THE ENGLISH SUB-WAELDEN EXPLORATION.—Some five years ago a number of scientific gentlemen in England undertook a scientific boring enterprise a short distance to the south of London, with the view of ascertaining the true character of the strata underlying that portion of the island of Great Britain, and as we understand it, on the part of some, with the expectation of developing sub-waelden coal measures, somewhere within 1,500 feet below the surface. This we believe is the first boring for purely scientific purposes ever undertaken in England, and the first extensive operation of the kind ever undertaken anywhere. The anger recently reached a depth of 1,850 feet; a careful and scientific record being kept of every foot of earth which it passed through. The object of the commission having been accomplished, work was discontinued a few months since. The anger employed was the circular diamond drill, by which the workmen were enabled to bring up solid cores of the various strata, two inches in diameter, from the lowest depth reached. For all purposes of a careful scientific examination these cores were as useful as an enlarged shaft into which the explorers could descend.

THE ASTEROIDS.—The number of these small planets which have thus far been discovered, is 159. The two last, Nos. 158 and 159, discovered respectively by Herr V. Knorre on the 4th, and M. Paul Henry on the 26th of last January, have been named Koronis and Emillia. The latter was discovered so long after its opposition that it is extremely desirable to obtain more observations of it soon, for the calculation of its orbit before it passes out of view; but, the planet being very faint (below the twelfth magnitude), such observations can be made only with the aid of a very powerful telescope.

A NEW INCANDESCENT LIGHT.—Hannecker, taking advantage of the properties of incandescence, has obtained a lamp of extraordinary brilliancy by directing the flame of a spirit lamp of special construction and fed by a current of oxygen against a cylinder composed of silicate of lime, magnesia and olivine, which latter is a natural silicate of magnesia. The cylinder composed of these earths is compressed by hydraulic pressure, in a manner not very different from the method employed for forming the cylinders used in the Drummond light.

An Antwerp chemist has lately discovered that the vapor of chloroform will not only extinguish the flames of petroleum vapor very speedily, but will even destroy its explosive and combustible proportions, if mixed with it. This discovery may prove capable of practical application in the prevention of fires.

FINE GOLD will melt at 2,016 deg. Fah.; pure copper at 1,994 deg.; fine silver at 1,873 deg.; and pure spelter at 773 deg.

The Mining Share Market.

The Mining Share Market.

Our stock tables will show the fluctuations in the various stocks during the past week. A considerable decline is apparent in the market, and on Tuesday and Wednesday there was quite a bad break.

There are a number of causes to which this decline may be attributed. The first and chief is the bad news from the Imperial mine. The north drift has again struck porphyry, and the greater part of the face is in that material and barren quartz. This news would naturally have more effect upon the Alpha stock than upon the Imperial itself, as the drift is now very close to the Alpha line, and should the ore body give out at this point Alpha would get no share of it. The Savage assessment didn't help matters much, it being double what was expected, and caused a deal of growling among its holders. It would naturally be supposed that the Consolidated Virginia dividend would have strengthened that stock if not other, but quite the reverse was the case, and it declined with all the rest. There has been an impression that it would declare a three dollar dividend this month, and its failure to do so weakened the stock.

The Woodside has levied an assessment of 25 cents per share, delinquent May 4th.

Savage levies an assessment of \$2 per share, delinquent in office May 8th, and day of sale May 27th.

The Consolidated Virginia and Belcher declare dividends of \$2 and \$1 respectively.

A meeting of dissatisfied Leopard mine stockholders is called to meet on Wednesday, the 12th inst., at the Fourth district court room. Rich developments are promised.

As will be seen by our Shareholders' Directory, Crown Point has levied an assessment of \$1 per share.

Machine vs. Hand Labor.

One great advantage which American manufacturers possess over the English is the greater and more diversified use of machinery in this country. A large amount of shop work that is done by machinery here is still done by hand work in England, and our machinery is thus more than a match for the cheap hand labor of England. The London *Times* long since called the attention of English manufacturers to this fact, and warned them of the evil consequences that would follow the persistent effort of the workmen of that country to keep machinery out of the shops and mines. In speaking of the watch making industry, in particular, the journal said: "If we would hold our own in Europe we must follow the example of the Americans, who have so successfully used ma-

day the American cotton and
features are underbidding the E

manufacturers are undertaking the largest in the cities of Manchester and Sheffield. The local trade of the United States with Sheffield for the first quarter of 1873 was over two and a quarter million of dollars; for the quarter ending March 31st of the present year that business footed up only a trifle over the half of one million, and the telegraph of Tuesday last informed us of the rumor that a large Sheffield house is about to remove its works to the United States.

ENCOURAGING PROSPECT.—California never had better prospects for a prosperous season than at this moment. The winter has been long and severe, and that is what the State needed. From every agricultural section of the State come the most cheering reports, with the exception of that part which has been overflooded, which is small compared with the vast area under cultivation. The mining counties will be well supplied with water the whole season, and the yield of gold cannot help being very large. Everything points to an unusually prosperous year. Our own county never looked better. The placer mines will turn out more than their accustomed yield, and the quartz mining interest looks well, and has a very good prospect of becoming more important than ever before. The railroad will be completed in a short time, so that communication with the outside world will be easier and more expeditious than heretofore. Money is at present a scarce commodity, but that condition of affairs, it is hoped, will not last much longer. When the times here are compared with those in other States, we of California ought to be perfectly contented, and we think most people are.—*Nevada Transcript.*

THE Territorial Enterprise, in an article commiserating the people on the arrangement that has been made by the Government to obtain the product of the bonanza mines, says: "The discount suffered last month by the Consolidated Virginia company on the month's production of their mine amounted to more than \$250,000. At this rate the loss to the company for the year (considering the reduction works to be added in the early spring) will swell to the enormous sum of \$5,000,000. It needs no very elaborate reasoning to show that this should not be so. * * * And really there must be a great deal of stock jobbing behind all this panic in silver. While in the last quarter of the century \$2,000,000,000 have been added to the gold product of the world, only about \$300,000,000 have been added to the silver product; only about one dollar to every three people of the nation which uses silver as their highest circulating medium."

MINING SUMMARY.

The following is mostly condensed from journals published in the interior in proximity to the mines mentioned.

California.

PINE'S MILL—Amador Ledger, April 1: Pine's quart mill at West Point bridge, which has been idle since the commencement of winter, commenced operation again this week. Pine had a large quantity of very hard rock ready for crushing. A pile of 150 tons he estimated a will go at least \$100 to the ton.

INCREASED TO TEN STAMPS.—Mace's five-stamp mill beyond Volcano, is to be increased to 10 stamps. Workmen are now engaged in putting in the additional stamps.

THE PRESENT MINE.—The pswa that reaches us concerning this mine is of a particularly gratifying character. The lodge is said to be 40 feet wide, and the present milling facilities are not equal to the task of crushing all the rock which might, with little additional expense, be taken from this immense ore body. It is reported that during the visit of Mr. Hayward, a few weeks back, it was fully determined to put up another 40-stamp mill this coming summer. We hope the report is correct.

PLYMOUTH TREMS.—Cor. Amador *Ledger*. April 1. Mining interest, also, as far as heard of in this vicinity, is looking decidedly better; and your correspondent is looking forward to quite an excitement in quartz mining in consequence of the Phoenix developing so splendidly. My belief is that this mine as it at present stands is equal, if not superior, to any gold mine on the Pacific coast. The immense mass of good ore which this mine shows at least 300 feet of very pure and rich ore, is estimated to be ranked in the first class of paying mines, and if it continues to improve in the same ratio as it did in sinking the last hundred feet, venture to say that by the time it reaches the depth of 1,200 feet (it is now only 900 feet) it will show a body of rich ore that will astonish old Californians.

BUTTE.
DITCH BROKEN.—Butte Record, April 1: From Dr. Brotherton we learn that about 60 feet of the old Snanner mining ditch on Butte creek, was washed out by the late storm. The owners intend fluming the break, we understand.

GOLD.—On Tuesday morning we stepped into Rideout, Smith & Co.'s bank, and in the 15 minutes that we remained there, the following lots of gold were received: One lot of 100 ounces; one lot 35 ounces, and one lot of 100 ounces. Besides this, the cashier had a bag full on his desk that had come in during the day immediately preceding. At \$17 per ounce, the value of the received on Tuesday morning amounts to \$2,414. The gold came from Butte creek, Mooretown and Thompson's flat. From the mountains come the report that they will not be able to begin to work as soon as usual, but that the water will last them much later than ordinary seasons. If so, the gold business will be very profitable for the remainder of the year by nearly one-half million dollars. This is a large sum, but several new mines have been opened that are paying well, and the old ones are doing better than in previous years.

ENGINEERING PARTY.—Mr. A. L. Knowlton, county surveyor, with party, left on Thursday morning for the forks of Butte creek, to commence the location of a water ditch from that point to the Butte creek mine near Centreville.

CAVALERAS.

STRANGE'S BONANZA.—Colavoras Chronicle, April. The rich deposit of gravel discovered by Mr. J. I. Strange, in his lot in the suburbs of town, continues to yield as largely as ever. The gravel is undoubtedly a portion of the French Hill lead, that was overlooked in early days. Joh says he is "willing to forgive the buyer for overlooking it."

GWIN MINE.—The slopes of the 1100-ft level in the Gwin mine are now opened sufficiently to furnish rock for 36 stamps. The batteries are kept in continuous motion, the yield being fully equal to that of any previous year. Work has commenced in the mine. The indications are that the 1100-ft level will produce a larger amount of money than any of those above it.

UPPER COUNTRY MINING.—Bro Yelkine.—Stoping is going steadily forward in the Uxampan, and first-class ore is being extracted. The mine never looked better nor was in a more flourishing condition than at present. There has been no cessation of work in the Uxampan since the sinking of the shaft. The Uxampan Sinking has been resumed in the Mina Rica. From the Glencoe district we have the most favorable report. The "reise" in the Sau Bruno is completed and the machinery for the new hoisting works is on the ground. The entire depth of the shaft is 275 feet. It is subdivided into three levels and divided into two compartments of three feet square each. The new hoisting works are to be driven by a 20 horse power engine. The machinery on the Grasshopper is now working splendidly, and it is expected to have the mine free of water in a few days. Gass & Co. have just had some exceedingly rich ore crushed and divided into two compartments. The first yielded 760, an average of over \$50 per ton. The rock was taken from a depth of 60 feet. Plenty more of the same sort in sight. A lot of rock from the Albers mine, 32 tons, paid \$20 per ton. Good for a wide ledge and uncracked rock. Good ore is being taken from the Albers mine to the depth of about 100 feet. It is expected to be resumed on the other mines of the district in a few days.

KERN.
THE ANTIMONY MINE.—Bakersfield *Courier*, April 10.—Messrs. Temple and Bushay, of San Eudido, are putting up the machinery for working the antimony mine and expect to have all in working order next month. They are preparing for a force of 150 men. Several families have already moved into the canon. The ore will be hauled to the depot and the teams will go.

Mr. Bushay is now in charge, and has made contracts for the season. The enterprise seems destined to create a sensation in mining circles, being something entirely new to this section, and very little understood.

KENNEDY MINE.—Cor Los Angeles *Express*, April 10. Prohibit one million dollars has been spent on the mine, and it has one of the finest mills in the state. The mine during the past summer has yielded fully 10 per cent. on the investment, and it is as yet but in the initial state of its development. It is a gold mine, and

at the present depth, ore is being taken out which averages \$100 to \$160 to the ton. The new slope, upon which work is about to be commenced, will yield, Mr. Lawrence thinks, easily \$100,000 a month. The mine is of immense size, running some six or seven miles distinctly defined. Mr. Lawrence has no hesitation in saying that he thinks it is the finest gold mine ever

LAKE.
THE MINES.—*Napa Reporter*, April 1: The Wall Street mine, located six miles west of Middletown, has n

been in operation for some time, owing to the great amount of water in the mine, but work will probably be commenced again next month. W. M. Moss, superintendent of the Wall Street, The Koor & O'Leary furnace is used, and when work is being done at the mine some 25 men are employed.

THE American mine also near Middletown, employs 25 men and ships 50 flasks of quicksilver per month. A tunnel in this mine, 400 feet in length, is nearly completed.

FATAL ACCIDENT.—*Nevada Transcript*, April 1: A very singular accident occurred to Dan Murphy on Monday forenoon about 11 o'clock, which resulted in his death about 10 hours afterward. He was employed in mining at the old Sozza mine, and while engaged at work

In out of the pits, was attacked by a large crowd of men, who looked out for a piece of the hanging wall, which was about to fall. Murphy, whose land was on the end of the pick handle, leaned his body back enough to avoid the falling mass, but caught his thumb and injured it quite severely. He came out of the mine and started home, but his hand was badly lacerated. On the way he met some parties who started to tell him what had occurred to him, and how sorrowful he was. He was being killed. While talking he sat down on a large boulder by the side of the trail, which is on a steep side-hill, and while there the rock gave way. In trying to save himself he fell backwards down the hill. The rock which had been loosened followed after him, and as his head caught up against another rock the boulder passed over him, and he was killed. He was two. He was taken to the residence of Mr. Beardsley where he died at half past 10 o'clock the same evening.

MONTICRISTO QUARTZ MINE.—*Mountain Messenger* April 1: This mine, formerly known as the Johnson Ledge, has passed into the hands of capitalists, and is now known as the Monticristo. It is located about three miles from Downsville, near the Eureka trail. The present trustees are Peter Buck, Oakland; T. G. Humphreys, D. G. Humphreys, E. R. Roberts and Augustus Wilder, Stockton. We learn that this company is possessed of abundant capital, and will pursue the work of development ahead as fast as men and money can do it. We think there is no doubt but they have a very valuable property.

Closed Down.—The Eureka quartz mill, at Jamison City, closed down a few days since. They were out of wood and provisions. Quite a number of the men employed have arrived here, and more will follow in a few days.

SOUTH FORK.—Tho E. O. V., about seven miles from town, is bringing in a ditch about one and a half miles long to a bed of gravel that prospects well. They expect to be in working order in three weeks. The Par Out company, farther down the river, have three cent to the pan and extensive deposit; think it is good fe

thres or f n ncl ars per day William & Co., at Bea
verville, or Kanaka flat, while mining for a back chan
nel some time ago, struck an old tunnel not known
before and found two skeletons in hammocks, and no
doubt they had been there 23 or 24 years. The bones
were completely bare and the hammock ropes and net
ting were perfectly rotten but had fiber enough to

tain them in their places. They were, no doubt, Kanakas, who had gone into the tunnel on a warm day, the ground caved in front of the tunnel, and foul air suffocated them. Williams found good pros ected directly under where the Kanakas lay. Witzel & Co. are reported doing well in a slide further down the river. The ground looks as if it might be extensive. The Broke Down Co., (a curious name) have found a promising place, and the prospect is being rigged for work. B. Wolford & Co. have gone to the rigging and will pay from one to three ounces per day. They are opening out for vigorous work. Altogether this section looks prosperous.

RICH MINDO GROUND NEAR COTTONWOOD.—Yreka Journal, March 29: We learn that Sam Cary, of Cottonwood, is taking out exceedingly rich quartz, which pays extravagantly. It seems to be detached quartz, greatly decomposed, but it is believed that it leads to rich permanent ledge below the surface. There are also other ledges, including the Lodi, which prospectors so well come time ago in the same vicinity, and the general belief is that there are no richer ledges than these around Cottonwood, if properly opened. Cottonwood is in the line of the great gold belt, and the stream, in the country. Large nuggets have been found at various times whenever it was possible to get at water. Several years ago a large piece was taken from the old Brass Wire claim, weighing 19 pounds, mostly gold, also a piece on Dutch or Priddy quartz, weighing over 10 pounds, which was sold for \$3,000.

WASHOE DISTRICT.
IMPERIAL EMPIRE.—Gold Hill News, March 30: The greatest public interest has been centered in the developments of the north drift on the 2000-ft level for the past two weeks. The ore in this drift has, during the time, undergone several changes, from good to poor and back again to a still better prospect, keeping the public mind in a state of perfect ferment. The situation has had ought to have reached a climax by this time. The drift has been in ore for a distance of 15 feet or more, and still continues in the same. The quality of the ore is good, and the chances for the same to extend into the Alpha ground now amounts to almost a certainty.

BALTIMORE AND AMERICAN FLAT.—Sinking the main incline shaft is making excellent progress. The 1030-ft drift has partly passed through the ledge on the 1030-ft level, which, at that point, is much more concentrated and better quartz than was ever found on either of the levels above. Drifts have been started both north and south on the vein in the face of both drifts are now in the line of the level. The above developments on this level are certainly looking much more hopeful than anything that has been found in the mine since the opening of the 400-ft level.

July 1.—The shaft is now down 80 feet below the 1700-ft level. It is the intention to open another station as soon as the 1800-ft level is reached. The melior southwest drift, on the 1600-ft level has shown a very encouraging improvement in the character of the quartz and ore penetrated during the past three days.

NORTH CONSOLIDATED VIRGINIA.—The shaft has sunk 77 feet during the past month, which, considering the amount of water hoisted by the tanks and the elasticity of the shaft, is equal to, if not a little ahead of, any work of the kind yet done on the line of the Comstock. The bottom of the shaft is still in porphyry, carrying favorable streaks of quartz. The shaft is now down 790 feet.

WEBBER.—Sinking the shaft has been suspended at a depth of 155 feet, pending the putting up of new steam hoisting works and machinery recently contracted for by Superintendent Hutchinson. The foundations will be laid and the necessary hoisting works building and carpenter and blacksmith shops erected.

LEO.—The ore prospects on the level recently opened at the bottom of the winze below the tunnel level are certainly on the increase, and a considerable amount of good pay ore has already been uncovered, ready for extraction and milling.

COOK, VIRGINIA.—Daily yield, 750 tons of ore, keeping the mills running up to their full working capacity. The ore breasts are yielding the usual quota of rich ore, and show no changes whatever. The mine never looked better than at this time. There is no change in

the east drift on the 1500-ft level to connect with the C. & O. shaft, the face of which is now outside of the ore vein.

CALIFORNIA.—Sinking the O. & O. shaft is going steadily, though slowly, forward, on account of the strong flow of water at the bottom. This water is easily taken care of by the pumps, but is a great annoyance to the workmen in the shaft. Ten feet have

METALS.

LONDON — Consols, 93 to 93½; Bonds, 102½;
QUICKSILVER in S. F., by the dash, near D. 72½ to 75.

SEVERAL FIRST CLASS SEWING MACHINES can be had at favorable rates to the purchasers, if ordered soon, from the Grangers' Business Association, N. E. Cor. Davis and California streets. S. F.

hasn added to the depth since our last report. The winze now being sunk below cross-cut No. 6 on the 1500-ft level has reached and been connected with the north drift on the 1550-ft level, and is now being continued below the 1550-ft level, to reach a point 50 feet below, at which it is desired to connect with the Ophir works for ventilation purposes. The bottom of this winze is still in the face of a very rich character. The main north drift on the 1400-ft level is steadily advancing along the east side of the ore vein, to connect with the Ophir for ventilation purposes, the face in clay, quartz and porphyry. This drift has about 50 feet yet to run to complete the connection.

OPHIR.—Daily yield, 150 tons of ore. The ore breasts are looking well and yielding the usual good quality of ore. Three mills, the Empire State, Nevada and Wulfeid are now kept steadily crushing ore from the mine. The east shaft has been closed out and reticulated to the 1700-ft level. The ore breasts on the 1600-ft level have again been opened in good shape for the extraction of ore when it is needed. The east drift on the 1400-ft level is steadily advancing, the face in a massive favorable formation that has yet been encountered in that direction. The new building, comprising the engine house, boiler house, steam factory, and an assay office, is steadily approaching completion. This incline machinery has been tested sufficiently to prove it to work in the most perfect manner. The yield of hollon for the present month will more than pay all the expenses of the mine.

LADY BAYAN.—A sufficient quantity of ore is extracted daily to keep the company's 10-stamp mill steadily running. No regular closing up has yet been made, but the amalgam in the pump is showing well, and it will not be many days now before the shipment of hollon will be regularly commenced. The ore stones on the 1700-ft level are showing finely. The rich vein of white ore recently opened on the 1700-ft level is looking very encouraging, and there is every reason to believe that it will open into a fine body of rich paying ore when it is reached by the west cross-cut now being run on the 380-ft level.

BULLION.—Sinking the main incline below the 1400-ft level is making splendid progress. Repairing the main north drift on the 1400-ft level has been suspended for a few days to give an opportunity to cut out a station and start a winze downward from this drift, to meet and connect with the raise now being made from the 1700-ft level for air purposes. This winze was commenced day before yesterday and will be pushed to completion with all possible speed. The northeast combination drift on the 200-ft level of the Imperial is evidently approaching the main ledge.

SILVERA NEVADA.—The shaft is now down 120 feet below the 1500-ft level. On the 1250-ft level the prospecting drifts are steadily advancing, with more favorable indications of a concentration of the ledge and the development of pay ore.

MONUMENTAL.—The shaft is now down 115 feet, the bottom in hard blasting rock. Eight hour shifts are being worked, and the developments pressed ahead with all possible vigor.

GROWN POINT.—Daily yield, 300 tons of ore. The cross-cuts run on the 1600-ft level have developed large bodies of quartz and low grade ore, but nothing that will pay the cost of extraction and milling. On the 1700-ft level the main east drift has reached the east or hanging wall at a distance of 168 feet from where the ledge was first struck. The vein at that point was almost all quartz and low grade ore, but nothing has yet been found that will pay for milling.

BALCH.—Daily yield, 455 tons of ore, keeping the mills all running at full capacity. The developments for the month of March will show, if any thing, that of February, insuring the payment of the regular dividend. The mine is looking well throughout, and there is an abundance of ore in sight to keep the mills running for months to come. The ore developments below the 1500-ft level are very promising. The erection of the new pumping machinery is steadily progressing.

YELLOW JACKET.—The recent development on the 1940-ft level still continues of a very favorable character. The finding of ore in the middle cross-cut has led to the starting of another cross drift at a point half way between the middle and south cross-cuts on that level. Preparations are also being made to start a winze downward on the ore formerly developed on the 1700-ft level.

BLACKBROOK.—Sinking the main shaft is making good progress, the bottom in green stone of a close, hard character. This rock is so close that but little water can now find its way through it. The shaft has now only a few feet to sink to reach the 800-ft level.

SUCOON.—This face of the main west drift on the 600-ft level is showing a steady improvement. The north cross-cut on the same level is steadily advancing, the face in soft porphyry. There is a considerable flow of water at the bottom of the shaft.

SAVAGE.—The pump and hoisting tanks have been stopped and the water now stands at about the 1300-ft level, without either rising or lowering to any considerable extent. Taking out the old machinery to make place for the new pumping machinery is going steadily ahead.

UTAH.—The shaft is now down 150 feet below the 500-ft level. The flow of water is still great, but it is easily handled by the pumps.

SILVER CURRY.—The Ramsdell mill is now kept running to its full capacity on ore from this mine. The ore breasts and slopes are all looking and yielding splendidly, and the fine ore body being opened up some 200 feet north of the present workings, is undoubtedly a valuable additional development.

SENIATOR.—This mine is again being put in order to resume sinking the main shaft. There is now but little water in the shaft, and the company intend to crowd the shaft downward, so as to reach and develop the ore vein on the deep levels.

CHOLLAR POTOMAC.—There is no change in this mine whatever since our last weekly report. No ore is yet being hauld to the mills.

SILVER HILL.—The pumps have the water well under control, and it is considerably expected that by to-morrow the water will be sufficiently reduced to permit the men to resume work in the drifts.

KOSOVE.—Both the north and south drifts on the 500-ft level are being pushed ahead, running parallel with the ore vein, both being in a very favorable formation.

GOULD & CURRY.—The repairs to the shaft and the connecting drift with the Best and Belcher, on the 1700-ft level, is being pushed steadily forward without any new features whatever to report.

HATE & NOBORS.—No water is being hoisted from the mine, and the water in the shaft stands at the same point as heretofore reported. Preparations for the erection of the new pumping machinery is making steady progress.

MINT.—Sinking the main shaft is making the usual good headway, the bottom still in soft ledge material of a very encouraging character.

BOSTON.—This is an old and favorable location situated just east of the Best & Belcher and Gould & Curry mines. The shaft is down 55 feet, the bottom is soft ledge material, and a very favorable formation.

PAUL SHERMAN.—The erection of the necessary building and machinery, for the prosecution of the development of the lower levels, is making good progress.

AMAZON & GLASCOW.—The new machinery is running splendidly, everything working with the utmost perfection. The water has been drained from the shaft. The water is doing no material damage to the lower levels whatever.

NORTH CARSON.—The pening out and development of the various levels progresses at a lively rate, and very encouraging assays are obtained, some of them up in the thousands. A very fine looking strake of vein of ore, discovered at the surface in grading for the new hoisting machinery, is widening out and showing very well.

BALCH CONSOLIDATED.—Work is resumed on this valuable mining claim, which lies directly west and adjoining the Nevada, on American flat. The Baltic has fallen into new hands.

COSMOPOLITAN.—Work is resumed and progressing well in the drift from the winze, showing some good bunches and streaks of ore. The face of the main tunnel continues in good milling ore, and the daily yield is about 40 tons per day.

PROSPECT.—Shaft sinking at the usual good rate, and everything working well. The diamond drill has been bored to the depth of 637 feet. At the depth of 420 feet it passed into the main ore vein and is still in it, the borings giving high assays and showing that a large and rich ore vein will be opened when this shaft gets down to it.

SUTRO TUNNEL.—Face of header in very tough and hard porphyry, making the rate of advancement somewhat slower. Considerable water is coming from the face. Total length of tunnel last evening, 12,670 feet. The widening out of the main tunnel to the regulation size progresses actively.

MEXICAN.—The north drift on the 1455-ft level is steadily advancing along the east wall of the ore vein, occasionally cutting bunches of ore of a very favorable character.

LADY WASHINGTON.—Sinking the shaft is making the usual good progress, the bottom in soft ledge material. There is a considerable flow of water at the bottom.

LEVIATHAN.—Shaft 876 feet deep. It has passed through a fine strake of ore and is now in splendid milling ledge material, which indicates the near proximity to a more extensive and valuable development.

SULLIVAN.—The west drift continues in the same splendid formation heretofore encountered, and due streaks and bunches of quartz continue to be met with, which give excellent assays. Vein fissure developed 500 feet now 260 feet in width.

NEW YORK CONSOLIDATED.—The prospecting drifts on the 300-ft level are making more favorable work advances. When the enlargement of the shaft is completed, it will then be one of the best working shafts on the line of the lead.

ORIGINAL GOLD HILL.—Some bunches of high grade ore have been met with in the south ore body this week, much better than yet met with.

FLORIDA.—The placing of the new machinery is steadily and energetically going ahead. Will be ready to start into full operation in the course of a week or ten days.

OVERMAN.—The repairs to the engines have been completed, and sinking the main shaft has been resumed. The flow of water is still very great.

TROJAN.—The erection of the new hoisting works is making steady headway.

BONNYTON.—The south drift on the 550-ft level is showing some very fine milling ore. The ore vein is opening out in that portion of the mine.

GLOBE CONSOLIDATED.—The north drift on the 300-ft level is steadily advancing, the face in quartz of a very favorable description.

UNION CONSOLIDATED.—The ore prospects in the bottom of the winze on the 1300-ft level is steadily on the increase.

BEST & BELCHER.—Repairing the main drift on the 1700-ft level is going steadily forward without stoppage or hindrance.

PICTOR.—Good advancement is made with the north drift, and excellent assays obtained from the streaks of quartz passed through.

CALDONIA.—Sinking the main shaft is making steady progress. The flow of water shows no change.

DEWEY.—This mine has again started up. The water is now being drained from the bottom of the shaft preparatory to sinking.

RED AND WHITE CROSS.—More streaks of low grade ore are met with, and the indications are becoming more favorable for soon reaching the ore body.

SUPERIOR.—An ore streak or spur of the main vein has been drifted upon which assays very high.

NORTH DAYTON.—Face of north drift shows improvement giving better assays.

NEVADA.—Face of north drift in low grade ore, with increased indications of nearing the main ore chimney developed in this level above.

(Continued on Page 236)

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

LAFAYETTE CONS. M. Co.—March 24th. Location: Virginia district, Nev. Capital stock, \$5,000,000. Directors—Mark Sheldon, A. Walrath, W. McCully, B. Oakland and H. R. Fowler.

MANTON & CO. THEATRICAL CO.—March 24th. Object: Manufacturing machinery appertaining to the process of treating ore, invented by Chas. F. Secor. Capital stock, \$25,000. Directors—C. F. Secor, A. C. Bradford, B. F. Baker, Chas. Chandler and A. D. Squire.

SOUTHERN PACIFIC COAST R. R. Co.—March 25th. Capital stock, \$1,000,000, in 10,000 shares. Object: Construct, conduct and maintain a railroad from a point on the Bay of San Francisco to Potrero point, otherwise known as Dunbarton point, in San Mateo county, through the counties of San Francisco, San Mateo, Santa Clara and Santa Cruz, on the most practicable route, to the town of Santa Cruz, with intermediate branch lines to Saratoga and New Almaden from such points on said railroad as may be designated by the Board of Directors. The estimated length of said railroad with its intermediate branches, is about 55 miles. The term of the incorporation is fixed at 50 years. Directors are Alfred E. Davis, Edward Barron, Seth Cook, George W. Kidd, Joseph Clark and J. Barr—all of San Francisco—and Cory Feehler, of Santa Clara.

RESUMPTION M. Co.—March 25th. Location: Storey county, Nevada. Capital stock, \$5,000,000. Directors—C. Churchill, T. B. Valentine, P. H. Blake, F. M. Smith and L. Aldrich.

CONSOLIDATED IMPERIAL M. Co.—March 25th. Location: Storey county Nevada. Capital, \$0.000,000, divided into shares of \$100. Directors—A. K. P. Harmon, J. D. Fry, C. L. Miller, J. H. Dublinson, Alpheus Bull, Wm. Norris and Joseph Sharon.

ELY G. & S. M. Co.—March 25th. Location: Lincoln mining district, Nevada. Capital, \$5,000,000, in shares of \$100. Directors—J. D. Hathaway, F. W. Gistman, Charles S. Benham, A. H. Wood and L. W. Mix.

TRUCKEE M. Co.—March 28th. Location: Storey county, Nevada. Capital stock, \$100,000. Directors, C. W. Fox, O. E. DeLong, J. N. Risdon, Robt. Ash and J. W. Gashwiler.

JUNO S. M. Co.—March 29th. Location: Nevada county. Capital stock, \$3,000,000. Directors, R. P. Leach, H. H. Clement, R. L. Taylor, Mark Shepherd and C. H. Stanton.

PITTS RIVER M. Co.—March 31st. Location: Copper City district, Shasta county. Capital stock, \$100,000. Directors—F. H. Wells, W. S. Brown, O. D. Durr, Geo. A. Treadwell and H. A. Dunning.

EAST UTAH S. M. Co.—March 31st. Location: Washoe. Capital stock, \$10,000,000. Directors—G. M. Peck, B. W. Mudge, F. H. Thomas and R. G. Ives.

MONITOR CONS. M. Co.—March 31st. Location: Columbus district, Nevada. Capital stock, \$5,000,000. Directors—R. R. Craig, W. F. Russell, T. F. Hopkins, John W. Prye and Geo. A. Treadwell.

LAFAYETTE G. AND S. M. Co.—March 31st. Capital stock, \$1,000,000. Directors—G. F. McPherson, John B. Webster, Thomas S. Fowie, Benjamin S. Lathrop and D. A. Dyer.

LIME ROCK RAILROAD CO.—March 31st. Object: To run a narrow gauge railroad from Monterey bay, in Santa Cruz to a point in the Santa Cruz mountains with a branch, the whole length of the road being 10 miles. Directors—G. W. Kidd, Josiah Applegate, David McKay, John Sedgwick and S. N. Putnam. Capital stock is \$200,000, of which \$10,000 has been subscribed.

Mining Decision.

Prior Locator.—Owner of the Ore at Intersection of Two Veins.

At the last term of the district court of Bonlder county, Colorado, says the *Denver Tribune*, an ejectment suit, involving the title to some valuable mining property, came up for hearing. The owner of the American mine, at Sunshine, had applied for a patent. The owner of the Bull of the Woods, which was a cross-ledge, filed an adverse claim. On the trial, Judge Belford claimed that when two lodes crossed each other, all that the prior locator could take was the ore at the point of intersection of the two veins, and not all the vein which was found inside of the side lines of the location. The court refused to adopt this view. A short time since, Judge Belford addressed a note to the Commissioner of the General Land Office, asking for a construction of section 14 of the mining act of 1872, and receiving the following reply, which is in accordance with the construction which he asked the court to give:

DEPARTMENT OF THE INTERIOR,
General Land Office.
WASHINGTON, Feb. 25, 1876.

JAMES B. BELFORD, Esq., Central City, Colorado.—Sir: Referring to your letter of the 15th inst., I have to state that the 14th section of the mining act of May 10th, 1872, provides "that where two or more veins intersect or cross each other, priority of title shall govern, and each prior location shall be entitled to all ore or mineral contained within the space of intersection: *Provided*, however, that the subsequent location shall have the right of way through said space of intersection for the purpose of the convenient working of the said mine."

The construction which has been given to this part of the law is that a party has a right to a patent for the number of feet along his lode or vein to which he has the local title, upon full compliance with the law and instructions: provided, however, that where another lode crosses, the ore at the space of intersection of the lodes belongs to the party who owns the prior location of the two.

The law clearly refers to cross lodes, and provides that the ore at the crossing of the two lodes shall belong to the first valid location, and hence where a patent issues for a mining claim which crosses one already patented, the surface ground in conflict is excepted from the second patent, but the subsequent patentee has the right, under his patent to his lode, for the distance patented, with the proviso heretofore referred to, viz: "that the ore at the space of intersection of the cross lodes shall belong to the prior location." L. K. LIPPINCOTT, Acting Commissioner.

End of the McGarrahan Claim.

In the Washington correspondence of the *Bulletin*, appears the following: The Press telegram from San Francisco that the New Idria company have arranged for a sale of their mines to Montgomery Blair of this city for \$1,000,000, is verified upon inquiry (though the negotiations were intended to be kept secret until finally consummated), but the accompanying statement of the company's officers that this is not a compromise with McGarrahan, fails of confirmation here. On the contrary, it is learned from unquestioned authority that the purchase is agreed to as the result of offers of compromise made to McGarrahan by the company's agent six months ago. Mr. Blair represents a number of capitalists who have been enlisted through the agency of General Butler, and who propose forming a new company, in which, of course, McGarrahan will have a large interest. That the chance of ownership is more than a mere commercial transaction, is indicated by the smallness of the price obtained for the property. With the consummation of this transfer, the "McGarrahan claim" will pass out of public view for the first time in many years, during which it has acquired historic interest and notoriety in connection with every branch of the government. In some of its phases it has been successfully, and often simultaneously, before the Courts, the Executive departments and the Congress of the United States; it has variously affected the public estimate of many prominent men; decided one Senatorial contest, and (by leading to the forced retirement of Secretary Cox) made a Cabinet.

FROM WARD DISTRICT.—Very cheering reports come from this district, says the *White Pine News*. No new strikes have been made in the Paymaster mine, but the ore body continues to increase as development is made and the character of the ore to improve in richness. Forty miners are employed in the mines. It is now an established fact that the owners of this valuable property will erect reduction works early this spring, or as soon as the roads will permit hauling. We are informed that two 30-ton water jacket furnaces have been ordered in San Francisco and will be erected as speedily as possible. This company are also the owners of valuable mining properties in the adjoining district of Lake, and have ordered the necessary machinery for the erection of a 10-stamp mill. The ores of this district are of a different character from those in Ward district, being fine milling ores and of high grade. The two districts are but a short distance apart. The Martin White company have very fine prospects ahead, and the time is not distant when they will have their furnaces and mill in operation, and a new and flourishing mining camp will be the result.

Montana Mines.

A correspondent of the *Helene Independent*, writing of Butte city and its mines, says: The town, in 1877, was one of the largest and most stirring places in the county, but taking the down grade, it had in the beginning of 1875 a population of less than 100. The principal occupation of these was placer mining, and but little was done towards the development of the silver and copper lodes of the district, believed to be rich, but largely held by non-residents, who had acquired perpetual (?) title under an act of the Bannack legislature, by simply staking, recording and discovering one well rock. The act of Congress of 1872, which went into practical effect January 1st, 1875, relieved our mining interests of the incubus which for 10 years had rested upon them, preventing active development. In proof of which I have only to add that some of the richest mines in the district, now being worked, were re-located very early in the morning of 1875, and before the old year had made many miles on the way down the western slope. By this time satisfactory returns had been received from copper and silver ores shipped East for reduction, a new impetus was given to quartz mining, and now more rich ore—ore that will pay to work and ship—is being taken out of the Butte mines than in any other district in Montana.

The Centennial Mill.

Owned by John Howe, is running successfully under the management of T. H. Manning. Work has been resumed on the Ferlin mill, and W. A. Clerk, trustee, is making strong efforts to have it in running order before the end of April. Capt. Plaisted has charge of the construction of the works, and is having everything done in a substantial and workmanlike manner. The first or main building contains the drying furnaces, battery of 10 stamps, settlers, and amalgamators. The second building (both mammoth structures) contains five reverberatory furnaces, and the pulp will be removed back and forth in a car. The reducing capacity of the works will be about 10 tons per day. That of the Centennial mill is now five tons, but was built with room and power to add another battery, which addition will most likely be made at an early day.

The Mines—Copper.

W. J. Parks is taking out copper ore for shipment, from the Parrott mine, at a depth of 150 feet and ore is better and the lode larger than above. Freeman & Co. have leased the Downs mine on same lode, and they are at present engaged taking out ore for shipping. Reese Anderson is taking out good ore on the extension of Parrott. Poznansky & Bro., on the Mountain copper lode, some distance above the Parrott, have a shaft down 40 feet, a seven-foot vein with three feet of good ore, some of which is now being shipped. Several leases for two years have been taken on divisions of the same lode, from parties not prepared to work them, some three or four houses are up and work going on. The Hattie Harvey, owned by Ramsdell, Butcher & Co., is showing nearly native copper and a good body of ore.

THE STAYTON QUICKSILVER MINES.—The *Holister Enterprise* says: We made a hurried trip to Staytonville on Tuesday, but as our business was not specially to inspect the famous mines of this locality, we are not prepared to give a detailed account of operations. A reduced force of men have been at work on the Stayton mines, and those of the Consolidated Wonder company all winter running tunnels, sinking shafts, etc., and developments are of the most satisfactory character. The richness of several of the leads in the Stayton group was substantially revealed several months ago, placing them beyond question in the first rank of quicksilver deposits; and any doubts that were entertained regarding the practical value of the Consolidated Wonder mines have been dissipated by the rich and promising strike of metal recently made in the Victoria tunnel. The future prospects are very encouraging indeed, and those who own stock in this corporation, we think, may rest satisfied that they have something worth holding on to. The Comstock and other prospects in that range also are looking well. A new furnace will soon be built on the Stayton mines and also on the Consolidated Wonder; and judging from the quantity of ore in sight, the Coast range mines of San Benito county will contribute to the world's supply a good share of quicksilver this summer.

BULLION DEPOSITORIES IN MINING DISTRICTS. The bill to utilize the products of American gold and silver mines, introduced by Congressman Banks a few days ago, commands itself to us a sensible measure. It provides that the Secretary of the Treasury shall establish in the great mining districts of gold and silver additional depositories and refineries, and receive from the miners and owners gold and silver, to be coined upon the certificate of a Government assayer, and issue a certificate of deposit therefor, payable to bearer, for such sums as depositories may desire; and when issued for more than \$500 on a certificate, may be made payable to order. Each certificate shall promise a return of the amount of gold and silver called for by the certificate, and shall be a legal tender in all transactions, the Government to be liable for the safe keeping of the gold and silver, and may become owner thereof by obtaining certificate through purchase or redemption. The Secretary is authorized to issue similar full-value certificates for coin that now or may hereafter be in the Treasury, reserving coin for their redemption.—*Ex.*

USEFUL INFORMATION.

Things Which it is Well to Know.

Irish stew is a dish never seen in Ireland.

Cat-out is not the gut of a cat, but of a sheep.

Kid gloves are not kid, but are made of lamb skin or sheep skin.

Arabio figures were not invented by the Arabs, but by the Indians.

Tuberose is no rose, but the tuberous palanin (*Polygonum tuberosum*).

Salad oil is not oil for salads, but oil for cleaning callets or salades—i. e., helmets.

Slave means noble, illustrious; but the term is now applied to the most ignoble and debased.

Black lead does not contain a single particle of lead, but is composed of carbon and iron.

Turkish baths are not of Turkish origin; nor are they baths at all. They are hot air rooms.

Salt is not salt at all, and has long been wholly excluded from the class of bodies denominated salts.

Cleopatra's Needle was not erected by Cleopatra in honor of that queen, but by Rameses the Great.

Prussian blue does not come from Prussia, but is the precipitate of the salt of protoxide of iron with prussiate of potassa.

Brazilian grass does not come from Brazil, or even grow in Brazil; nor is it grass at all. It consists of strips of palm leaf, and is chiefly imported from Cuba.

Whale-bone is no bone at all; nor does it possess any properties of bone. It is a substance attached to the lower jaw of the whale, and seems to strain the water, which the creature takes up in large mouthfuls.

Sealing wax is not wax at all; nor does it contain a single particle of wax. It is made of shellac, Venice turpentine, and cinabar. Cinabar gives it the deep red color, and turpentine renders the shellac soft and less brittle.

Burgundy pitch is not pitch, nor is it manufactured or exported from Burgundy. The best is a resinous substance, prepared from common frankincense, and brought from Hamburg; but by far the largest quantity is a mixture of resin and palm oil.

Buttons from Pebbles.—Immense quantities of buttons, manufactured from pebbles, are produced in Paris, and sent to almost every part of the globe. These pebbles, which are of crystallized felspar, containing as little clay and lime, or lime salts as possible, are reduced to powder by heating them to cherry red and then plunging them into cold water. The powder is separated from its impurities by being passed through a wire gauze sieve, and is next well stirred in water. The residuum is treated with a quantity of hydrochloric acid, varying from three to 10 per cent., to free it from the oxide of iron, which would give the buttons a reddish hue in the baking process. One hundred pounds of powder are mixed with two of chloride of sodium and four of flour paste, dissolved in five quarts of water; the whole is then passed through the sieve, and dried to a proper consistency for molding.

Brightening Iron.—When taken from the forge or rolls, the articles are placed in dilute sulphuric acid, (1 to 20,) then washed clean with water and dried with sawdust; they are then dipped for a second or so in nitrous acid, washed carefully, dried in sawdust, and rubbed clean. It is said that iron goods thus treated acquire a bright surface, having a white glance, without undergoing any of the usual polishing operations. It is stated that the action of the sulphuric acid is increased by the addition of a little carbolic acid, but it is difficult to see what effect this can have.

To Take the Rust off a Plowshare.—Take a quart of water and pour slowly into half a pint of sulphuric acid. The mixture will become warm from chemical action; put it on the iron and let it remain there until it evaporates. Then wash it again. The object of this is to give the acid time to dissolve the rust. Now wash with water, and you will see where the worst spots are. Apply some more acid, and rub on those spots with a brick. The acid and the scouring will remove most of the rust. Then wash the mold-board thoroughly with water to remove the acid, and rub it dry. Brush it over with petroleum or other oil, and let it be till spring.

Glass Cement.—A cement to stop cracks in glass vessels, to resist moisture and heat, is made by dissolving casein in a cold saturated solution of borax. With this solution paste strips of hog's or bullock's bladder, softened in water, on the cracks in the glass, and dry at a gentle heat. If the vessel is to be heated, coat the bladder on the outside, just before it has become quite dry, with a paste of a rather concentrated solution of soda and quicklime or plaster of Paris.

Black Pepper is made by grinding the dried berry of a climbing vine native to the East India. White pepper is obtained from the same berries freed from their husk and rind. Red or cayenne pepper is obtained by grinding the scarlet pod or seed vessel of a tropical plant that is now cultivated in all parts of the world.

PETROLEUM AS A LUBRICANT FOR TURNING TOOLS.—Considerable comment has appeared of late in foreign mechanical journals relative to the use of petroleum as a means of facilitating the action of turning tools in operating upon very hard alloys. A writer in *Les Mondes* states that a mixture of seven parts zinc, four copper and one tin, resisted all tools even when the latter were tempered to extreme hardness. As soon, however, as the cutting edges were moistened with petroleum, the alloy immediately yielded and was turned without difficulty. It is also said that, by using a mixture of petroleum and turpentine, steel annealed to straw yellow can likewise be turned. We know of no direct practical confirmation of this, but should be glad to hear from any of our readers who may test the suggestion. Meanwhile we shall experiment for ourselves, and note the result as soon as perfected.—*Scientific American*.

A NEW NICKEL PLATING SOLUTION, said to yield beautiful results, is prepared by mixing the liquid obtained by evaporating a solution of one-half ounce nickel in aqua regia to a pasty mass and dissolving it in one pound aqua ammonia, with that obtained by treating the same quantity of nickel with a solution of two ounces cyanide of potassium in one pound of water. More cyanide renders the deposit whiter, and more ammonia renders it grayer.

ENGLASS CEMENT.—Mix ground white lead with as much finely powdered red lead as will make it the consistency of soft putty. Another is to mix equal parts of white lead and red lead, and as much linseed oil as is required to give it the proper consistency; or boiled linseed oil and red lead mixed into a putty. These cements are used for making metallic points round.

IS LAMPGLASS SOLUBLE?—The substance known as lampglass always contains more or less resinous and tarry matters, that are soluble in oil of turpentine, benzine, naphtha, etc.; but the purified lampglass (carbon) is itself insoluble in any menstruum.

HOW TO MARK TIN CANS WITH A PEN.—Squeeze the juice of a lemon into a china or porcelain cup, and put in a small bit of copper. Let it stand for a day or two, then use it with a quill pen as with ink.

A FRENCH chemist has taken out a patent for making ink for printing, lithographing, etc., from the heavy oils and residuums of petroleum. He claims that ink made from these oils possesses great advantages over other kinds.

INDIAN OR CHINESE INK is formed of carefully purified lampblack and size, or animal glue, with the addition of perfumes, not necessary, however, to its use as an ink.

GOOD HEALTH.

Colored Light as a Cure for Insanity.

Dr. Ponza, director of the Insane asylum at Alessandria (Piedmont) having conceived the idea that solar rays might have some curative power in diseases of the brain, communicated his ideas to Father Secchi, of Rome, who replied: "The idea of studying the disturbed state of lunatics in connection with magnetic perturbations, and with colored, especially violet light of the sun, is of remarkable importance." Such light is easily obtained by filtering the solar rays through a glass of that color. "Violet," adds Father Secchi, "has something melancholy and depressing about it, which, physiologically, causes low spirits; hence, no doubt, poets have draped melancholy in violet garments. Perhaps violet light may calm the nervous excitement of unfortunate maniacs." He then, in his letter, advises Dr. Ponza to perform his experiments in rooms the walls of which are painted of the same color as the glass panes of the windows, which should be as numerous as possible, in order to favor the action of solar light, so that it may be admissible at any hour of the day. The patient should pass the night in rooms oriented to the east and south, and painted and glazed as above.

Dr. Ponza, following the instructions of the learned Jesuit, prepared several rooms in the manner described, and kept several patients there under observation. One of them, affected with morbid taciturnity, became gay and affable after three hours' stay in a red chamber; another, a maniac who refused all food, asked for some breakfast after having stayed 24 hours in the same red chamber. In a blue one, a highly excited madman with a straight waistcoat was kept all day; an hour after he appeared much calmer. The action of blue light is very intense on the optic nerve, and seems to cause a sort of oppression. A patient was made to pass the night in a violet chamber; on the following day he begged Dr. Ponza to send him home, because he felt himself cured; and, indeed, he has been well ever since. Dr. Ponza's conclusions from his experience are these: "The violet rays are, of all others, those that possess the most intense electro-chemical power; the red light is also very rich in caloric rays; blue light, on the contrary, is quite devoid of them, as well as of chemical and electro-chemical. Its beneficent influence is hard to explain; as it is the absolute negation of all excitement, it succeeds admirably in calming the furious excitement of maniacs."

Eat Celery.

We notice with satisfaction that celery is becoming more common and cheaper in our markets; its cultivation cannot be too strongly recommended to farmers, as by its production they not only grow a profitable plant, but confer a favor on the community, as the habitual daily use of this vegetable is much more beneficial to man than most people are aware of.

A writer who is familiar with its virtues says: "I have known many men, and women too, who from various causes had become so much affected by nervousness that when they stretched out their hands they shook like a-p-n leaves on a windy day, and by a moderate daily use of the blanched footstalks of celery as a salad they became as strong and steady in limb as other people. I have known others so nervous that the least annoyance put them in a state of agitation and they were in constant perplexity and fear, who were also effectually cured by a moderate daily use of blanched celery as a salad at meal time. I have known others to be cured of palpitation of the heart. Everybody engaged in labor weakening to the nerves should use celery daily in the season and onions in its stead when not in season."

To this we may add that a prominent New York druggist draws in winter from his soda fountain a hot extract of celery, mixed with Liebig's meat extract, under the name of ox-celery. It is a nourishing drink at lunch time, far better than coffee or tea, and is doing a great deal in this neighborhood to promote temperance. Diluted drinks are no better for a man than a whip is for a horse to make him work; oats are better than the whip, nobody will deny that, and to keep up the strength of a human being ox-celery or beef tea is better than whisky, but this fact many do not appear to know or realize.

But to return to celery. We give it almost daily to our canary birds and it cures them of fits; they are little animals, with very delicate nerves, easily frightened, and therefore they need such a remedy very much, and the relish with which they take it is a proof that their instinct guides them to eat what is good for them.

A manufacturer of perfumery of our acquaintance some years ago commenced to prepare an extract of celery seed, put up in bottles, and intended to give strength to old or exhausted persons, who, by over-indulgence, have reached such a state as to require restoratives.—*Boston Jour. Chemistry*.

Health Maxims.

We breathe in sleep about 15 times every minute.

If the bowels are loose lie down in a warm bed, remain there and eat nothing until you are well.

Do not allow yourself to read a moment in any reclining position, whether in bed or on a sofa.

Never swallow an atom of food while in a passion, or if under any great mental excitement, whether of a depressing or elevating character; brute won't do it.

The importance of wholesome water and good sewerage to every angle dwelling cannot be over-estimated, and any city neglecting this vital matter must expect to suffer at all times, and particularly when an epidemic of any kind sweeps over the country.

To be able to lie down at night and fall to sleep within ten minutes, and to know no dream or waking until the morning comes, and then to bound out of bed full of health, freshness and good humor, is a blessing well worthy the warmest outpourings of a thankful heart towards Him who giveth us all things richly to enjoy.

The great regulator of sleep is exercise; it is the best antidote in the universe, and it is the only one that is always wholesome and natural. If you cannot take much exercise, take a little, and every second hour increase the distance, and soon you will be able to walk a mile more easily than you walked the first hundred yards.

If an action of the bowels does not occur at the usual hour eat not an atom until they do act, at least for 36 hours; meanwhile drink largely of cold water or hot tea, and exercise in the open air to the extent of a gentle perspiration, and keep this up until things are righted; this one suggestion, if practiced, would save myriads of lives every year, both in city and country.—*From Dr. Hall's Maxims*.

SHAMPOONING (SCALPINO).—An intelligent writer in the *Chicago Tribune* protests against the practice of shampooing. He says this repeated application of stimulating washes destroys the hair, and is almost equivalent to scalpings. He is surprised that there are any men with full heads of hair left, and advises all young men to discontinue this pernicious practice.

Put some extra hedging on the foot of the bed at night to give the feet added warmth, and to be drawn up higher if needed before morning. The feet need special attention, as one of the best rules of health is to keep the head cool and the feet warm. Don't encourage cold feet by wearing shoes a size too small, for this will check the circulation.

A DOCTOR, on calling upon a gentleman who had been some time ailing, put a fee into the patient's hand, and took the medicine himself which he had prepared for the sick man; he was not made sensible of his error till he found himself ill and the patient getting better.

DOMESTIC ECONOMY.

Vegetables.

All green vegetables should be as fresh as possible. Put them into cold water with some salt in it, for about ten minutes, to clear from soil or insects. If not quite fresh let them remain in the water some time longer; drain in a colander and put them into a pan with plenty of boiling water, adding salt and a small piece of soda; cover the pan till boiling, but not afterward; then boil quickly, and carefully remove any scum which may rise. Do not allow them to remain in the water after they are done, but immediately drain them in a colander and finish each kind, as directed in recipes. Peas and spinach do not require so much water as most other green vegetables, but only just sufficient to cover them. Cauliflowers and brocoli require especial care in boiling, as the flower is easily broken and their appearance spoiled; boil them quickly for a few minutes, and then moderately till tender, which may be easily ascertained by trying the stem with a fork. All vessels used in cooking vegetables should be particularly clean. Soft is preferable to hard water in cooking all kinds of vegetables. Potatoes are in universal use, and yet how few know how to cook them well! "A well boiled potato is a thing purely ideal—it has never come out of the pot, in the experience of living man." This is too strong; but there is very much room for, and need of, improvement in the science of cooking a potato. To do it well, the matter must be studied, and not performed by routine. They differ very much, even those grown in the same field and from the same seed. A good potato, well cooked and served up, is a luxury, which, unfortunately, few people know how to accomplish, or will not give themselves the trouble to do.

Choice of Milk.

Cow's milk differs greatly in quality, some being rich and other thin and watery. In choosing a family cow it is well to hear this in mind, and select only those that are healthy and give the very best milk. They should also be fed on the best of food and allowed pure soft water to drink. The practice of feeding cows on garbage, swill slops, distillery feed, and of keeping them confined in close, filthy, unventilated stables, is one which seriously deteriorates the milk and should ever be avoided.

Those who live in cities cannot of course keep cows, and so they must depend on the market for their supply of milk. In such cases insist on having the best article and refuse to use that from distillery-fed cows, or that diluted with water. A little attention to this subject will enable any one to secure a good article. It is the laxity of purchasers of food in not demanding the best that makes it so easy for the dealer to palm off adulterated and inferior articles upon thoughtless people. If the poor would do this it would improve their own and their children's health wonderfully. The milk supply of a city has a great deal of influence for good or evil on the health of the children. In England this question is getting to be a very important one. The *Food Journal* says that "perhaps the most serious and destructive change in the nutrition of the poor is their almost total privation of milk. Infantile sickness and mortality depend largely on this want." There the occupation of mothers in factories and work shops deprives many thousands of infants of their natural food—breast milk.

FRENCH HOUSEHOLD ECONOMY.—The French butcher separates the bones from his steaks, and places them where they will do his most good. The house wife orders just enough for each person, and no more, even to the coffee. If a chance visitor drops in, somebody quietly retires, and the extra cup is so provided, but nothing extra by carelessness of intention. When the pot has boiled, the handful of charcoal in the little range is extinguished, and waits for another time. No roaring stoves and red-hot covers all day long for no purpose but waste. The egg laid to day costs a little more than the one laid last week. Valves are nicely estimated, and the smallest surplus is carefully saved. A thousand little economies are practised, and it is respectable to practice them. Cooking is an economical as well as a sanitary and gustatory science. A French cook will make a franc go as far as an American housewife will make three, and how much hotter than the American Bridget nobody knows—we should probably be greatly astonished, could the computation be made, how much of the financial recuperative power of France is owing to her soups and her cheap food; better living, after all than the heavy bread and greasy failure of our culinary ignorance.—*Springfield Republican*.

A soon cook is not the one who uses the most and richest ingredients, regardless of the expense; but she who audits economy, and is able to concoct a delicious meal from scanty materials.

EGG SANDWICHES.—Boil fresh eggs five minutes; put them in cold water, and when quite cold peel them, and after taking a little of the white off each end of the eggs, cut the remainder in four slices. Lay them between bread and butter.

Subscriptions payable in advance.—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so?

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, April 8, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Allen's Fracture Bed, 225-233. The Emma Mine Scandal; Gems and Precious Stones; Notices of Recent Patents, 232. Sulpho-Carbonate Treatment of Vines; Our Reporter Abroad, 233. Patents and Inventions, 236.

ILLUSTRATIONS.—Allen's Fracture Bed with Appliances, 225. Effect of Sulpho-Carbonates on Vines, 233.

CORRESPONDENCE.—Botanical Excursions; Placer County Mines, 226.

MECHANICAL PROGRESS.—The Use of Steel in Boilers and in Locomotive Fire Boxes; Reverberatory Furnace and Cupola Iron; Boiler Tube Stopper; Small Steam Engines; The New Grinding Process; A New System of Railway Signaling, 227.

SCIENTIFIC PROGRESS.—Scientific Weather Prediction; Seeds Germinating in Ice—Interesting Scientific Experiment; Animals Can Absorb Atmospheric Nitrogen; A Worthy Son of a Scientist; New Property of Glycerine; A New Fossil Reptile; The English Sub-Warlike Exploration; The Asteroids; A New Incandescent Light, 227.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 228-9.

MINING SUMMARY from various counties in California, Nevada, Utah and Idaho, 229-230-236.

USEFUL INFORMATION.—Things Which it is Well to Know; Buttons from Pebbles; Brightening Iron; To Take the Rust off a Plowshare; Glass Cement; Petroleum as a Lubricant for Turning Tools; Engineers' Cement; Is Plumbago Soluble? How to Mark Tin Ores with a Pen, 231.

GOOD HEALTH.—Colored Light as a Cure for Insanity; Eat Celery; Health Maxims; Shampooing (Scalp), 231.

DOMESTIC ECONOMY.—Vegetables; Choice of Milk; French Household Economy; Egg Sandwiches, 231.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 236 and other pages.

MISCELLANEOUS ARTICLES.—Sales of Mining Property; Liability of Stockholders; Address by the Centennial Committee, 226. New Incorporations; Mining Decisions; End of the McGarrahan Claim; From Ward District, Montana Mines; The Stanton Quicksilver Mines; Bullion Depositories in Mining Districts, 230. Miners' Organization; Capital Stock Fully Paid Up, 234. Spring Valley District, 238.

NEW ADVERTISEMENTS.

Mining Sales—Golden Sun Gold Mining Company; Josephine Grand Mining Company, Assessment—Lady Frank in Gold and Silver Mining Company.

CALIFORNIA OLIVE OIL.—One of the New York dailies remarks that it may not be generally known that a considerable quantity of California olive oil is finding an appreciative market there, and is coming into quite general use in hotels and restaurants. Samples of the oil were recently submitted by a prominent restaurant keeper to a party of his patrons, who were good judges of the article, for an opinion. After critically testing it, they unanimously reported it a first-class article, and were much astonished on being informed that it was of California production. The article is put up by parties at Los Angeles in cans and cases, and is sold in New York at a slight reduction from the rates of imported oil. Owing to the prejudice against home products, the agents have been obliged to label it Plagniol, a well known French brand.

AIR CURRENTS.—At the Sutro tunnel they have one of Cassel's air meters, a portable gauge for measuring the velocity of currents of air in mines, ventilating flues, etc. By this instrument the speed of the air in the tunnel was measured last Wednesday. The Independent says: At shaft No. 2, 100 feet per minute, or 1.13 miles per hour. At shaft No. 1, west side, 270 feet per minute; east side, 125 feet per minute; at mouth of tunnel, 35 feet per minute.

The Emma Mine Scandal.

Rumors of rich strikes in the Emma mine have been again and again industriously circulated, and needy men, calling themselves miners, have addressed letters to some of the English vendors complaining of the management of the mine and offering their services to superintend the mine for them. One of the American vendors, who made a large fortune by the sale of the mine to the English dupes, is reported to have claimed that the new company had employed an incompetent superintendent, and that the mine was shockingly managed. In an interview with a newspaper reporter this gentleman says:

"While going on well, and with excellent prospects, they struck a fault in the mine, the same as striking a flat wall. Instead of following down on the seam to another body of ore, they ran through the drift and quit. Another company, known as the Bay City, has run a tunnel in from Alta, and found a fine body of ore within the Emma, but below, said to be of a higher grade than that in the upper workings of the mine. This should have been found by the Emma mine people, according to the ordinary rules of mining, within 60 or 90 days of the time of finding the fault. In that event the stock would have suffered very little on account of the discovery of the break."

The above conveys, or is apparently designed to convey the idea, that there was ore left in the mine to work. On the other hand, men of unquestionable integrity, such as Mr. Clarence King, Mr. Andrew Murray, of London, Mr. Blackwell, Prof. Blake, Mr. Attwood, and a host of others, after a very careful examination of the works, report the great Emma bonanza to be worked out. In the first report of Prof. Blake, made July, 1871, it appears that the mine was nearly worked out. In that report the Professor said:

"At the present rate of extraction the mine will soon be stripped, and, for the present, practically exhausted, at least for some time, or till another body of ore can be found."

This paragraph, and so much of the report as related to the matter of the mine being exhausted, appears from a report of the English directors, dated April 29th, 1875, to have been "carefully suppressed," until after the sale.

In support of the correctness of the report of Prof. Blake, we give the following brief extracts from other reports made to the English company after they had effected their purchase: Clarence King, under date of June 11th, 1873, said: "The great Emma 'bonanza,' the object of such wide spread celebrity, the basis of such extravagant promises, is with insignificant exceptions worked out, and the future of your company is hung on a mere geological chance, which may be eternally against you; and if in your favor may only be secured by the wise expenditure of time and money."

Andrew Murray, F. L. S., London, Aug. 15th, 1873, said: "In my opinion, the famous Emma mine is exhausted, and nothing more is to be expected from it but the leavings of the old workings."

Mr. Blackwell, manager of the Ophir mining and smelting company, Uist, reports, June 7th, 1873: "The future of the mine depends entirely upon virgin ground, and to explore this you must be prepared to wait some time and spend a large amount of money in developments."

Mr. Attwood, in his report of April 30th, 1874, says: "The future chance of finding a new deposit of ore rests most undoubtedly on a geological problem; but as long as you have any funds in hand I do not think your property should be abandoned, but explorations carried on, as I have advised, and that, too, in a careful and economical manner."

Much has been said and great hopes have been expressed by the vendors, of the chances of finding another deposit of ore in the claim.

We have made enquiries of competent parties conversant with the claim, and the answer given to us was nearly in these words: "That the enclosing rock of the Emma mine deposit was a bed in lower silurian limestone, the deposit having the same strike and dip as the enclosing rock. That though called a vein or lode by some, that it could hardly be termed such according to the generally accepted meaning of the word. That it had no foot or hanging wall so specially characteristic of true veins or lodes, and that the ore bearing character of the deposit gradually disappeared in depth, and on either side, and that the limestone forming the main bulk of the gangue increased by degrees till at last it merged into the unaltered limestone rock; consequently there is no ore left to work, and the chances of finding another deposit anything but encouraging. Had it been a true vein or lode, a fissure, die, or caving the limestone beds, and causing a displacement of them, with well defined walls, like the large lead veins in the limestone formation of the north of England, it would have been different and the prospect of meeting with more ore good."

A MARL DEPOSIT IN KENTUCKY.—Kentucky has just struck a bonanza in the shape of the discovery of a vast bed of marl, which, it is said, underlies an area of some twelve thousand square miles, mainly that part of the State where it appears to be most needed, the tobacco-growing counties. Twelve thousand square miles is nearly one-third the area of the entire State.

Gems and Precious Stones.

(Written for this Press by HENRY G. HANES.)

(Continued from last week.)

A.—Diamond, Jet and Cannel Coal.

The diamond is pure carbon crystallized. Chemically it does not differ from charcoal, and is also nearly identical in composition with graphite.

It is the hardest of all known substances. Its specific gravity is 3.529 to 3.55. Diamonds are not always colorless, and this fact renders their determination difficult. They are sometimes tinged yellow, red, orange, green, brown, blue, rose red and often black. When the color is decided they are more valuable than when limpid. When light colored, they are said to be "off color." The fracture of the diamond is four-fold, parallel to the faces of the octahedron. The fragments are octahedral or tetrahedral. It strikes fire with steel, surface often rough or striated, sometimes covered with a scaly crust. The touch of the diamond is cold. When the cut gem is breathed upon the luster is lost for a moment, when defects are seen.

Diamonds found in river beds are generally in rolled masses, while those found imbedded in the formations peculiar to their locality are covered with an earthy pale gray, yellow, or rose-red coating. The texture of the diamond is lamellar.

The diamond exhibits a beautiful play of colors in the direct rays of the sun, or bright artificial light. To its luster has been given the name of "diamond luster," or "adamantine luster." Its refraction is simple, but it possesses this power in a higher degree than most other minerals of equal specific gravity. In consequence of its extreme hardness, it can only be cut by its own powder. The common saying, "Diamond cut diamond," is exceedingly expressive.

When the diamond is rubbed, it becomes positively electrical, even before being cut, in which it differs from all other gems. When, after exposure to direct sunlight, it is suddenly placed in darkness, it shows phosphorescence, and the evolution of light continues for some time. It is not acted upon by any acid or alkali. But it may be consumed and completely oxidized to carbonic acid at a high heat in the atmosphere. It is so difficult to burn that the ordinary blow-pipe flame has no effect upon it. It may be heated to whiteness in a closed crucible without change, but it begins to burn in a muffle at the melting point of silver. At a high heat with nitrate of potash it is rapidly decomposed.

Miners are generally not familiar with the appearance of diamonds in the rough state, and would most likely mistake them, if found, for chalcedony or some similar mineral. If in crystal form, it would be to them a crystal only—interesting for the moment, to be soon thrown aside as useless. I have heard of a case where a beautiful crystal, supposed to be a diamond, being found in some placer mine in California, was put to the following test: It was placed on an anvil and struck a heavy blow with a sledge hammer, it being assumed that the diamond, being the hardest of known substances, could not be broken. This idea is more ancient than is generally supposed. The statement has been made by Pliny, but it is doubtful if he ever made the experiment himself. In speaking of adamas, he says that it cannot be crushed, but would split hammers and anvils in the attempt.

It is certain that this is a mistake. The diamond can be split on the edge of a knife, and even a light blow with a hammer might destroy the most costly gem.

The diamond is supposed to be of vegetable origin, and is believed, by those who have studied it carefully, to be produced by slow decomposition of vegetation or bituminous matters. It is generally colorless, but always transparent (except in case of the black diamond, which is opaque,) generally crystallizes in octahedrons, but often found in rounded masses, occasionally in curious irregularly concretionary forms, like chalcedony or semiopal. Frequently the faces of the crystals are curved, sometimes they take a nearly spherical form, having 48 faces.

It requires practice to judge of the diamond in its rough state. A rough diamond of the first water would be hardly recognized by the uneducated eye as a valuable gem. In describing the diamond, many of its characteristics are visible only in its cut state. Half the stone is sometimes cut away before a perfect gem can be produced. The diamond washers of Brazil rub the stones together and produce a peculiar grating sound, from which they assume to judge of their value.

There is a peculiar appearance about a rough diamond which can hardly be described. I question if any written description would convey to the reader a correct idea of what they are exactly like. It is easy to say that they possess a peculiar luster, like spermaceti, but who would feel certain of the identity of a diamond from such a description. Once seen, this peculiar luster becomes impressed on the mind. To educate the eye, models of rough diamonds are made at Amsterdam for the use of prospectors, and they are found extremely useful.

The diamond has been found massive in Brazil. In this form it cuts glass, scratches quartz and topaz. Has a specific gravity of 3.27 to 3.52, and is nearly pure carbon, being completely consumed in oxygen gas. It occurs in kidney-shaped, irregular masses, exterior generally black, sometimes resembling graphite,

has a somewhat resinous luster, sometimes takes very singular forms. The outer coating black and resinous, interior crystalline, vitreous and lamellar, like the diamond. It has been used in powder to cut other diamonds. The diamond cutters call them "cheese stones."

A diamond may be burned away on a piece of platinum in the flame of a powerful blast blow pipe.

Sir David Brewster found cavities in the Koh-i-noor, and other large diamonds, with the microscope. Black diamonds he found to be opaque from a multitude of such cavities. One large diamond having a black spot in it was cut in two, and the defect was found to be vegetable mud enclosed in the crystals.

(To be Continued.)

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency the following are worthy of mention:

FURNACE FOR STEAM BOILERS.—Michael Laufenberg, S. F. This invention comprises a new arrangement for feeding straw to the furnaces of steam boilers and burning it as fuel for generating steam. It consists of a peculiarly constructed door which can be either applied in place of the ordinary furnace door, or it can be located directly in front of the grate bars and extend entirely across the front of the furnace. The grate bars are suspended on journals at or near the middle of the furnace, and their rear ends are weighted. The inventor then connects the door with the front ends of the grate bars so that whenever the door is opened and closed the grate bars will be shaken or jarred, while the weighted rear ends of the grate bars serve to close the door. The furnace front is cut entirely away from a line directly in front of the surface of the grate bars, downward. The sides and bottom of the furnace are also extended forward so as to form a projecting box in front of the furnace below the level of the grate. The front half of the grate bars projects far enough forward to have their front ends strike against the lower edge of the boiler front, where it is cut away. A door is placed at an incline directly above the box, so that its inner or upper edge will also rest upon the forward ends of the grate bars, while its outer or lower edge is pivoted to the sides of the box. A flange is screwed to the lower edge of the boiler front, outside of the furnace. This flange is inclined upward at an angle opposite to the angle of the door, and can be formed by merely turning a portion of the boiler front upward, thus forming a flaring or V-shaped approach to the doorway. The straw is fed to the furnace by placing it in the V-shaped angle between the door and flange, and by pressing it forward with a fork the upper end of the door is depressed, carrying with it the forward end of the grate bars until an opening is made sufficiently large to admit the straw. It is then pushed into the furnace with the fork, and as the fork is withdrawn the superior weight of the rear end of the grate bars will raise the forward end and close the door, the striking of the forward end of the bars against the lower edge of the boiler front producing a jar which will clear the bars from cinders. This construction enables the inventor to feed the straw to the furnace at any point in its width, whereas the ordinary door arrangement only provides a limited opening so that the straw is all fed in one place and creates a heap of cinders at that point, which prevents the proper burning of the straw by choking off the draft. By placing the door below the grate bars and feeding on a level with them, the fresh straw which is introduced disturbs the cinders and is fed directly into the hottest part so that it is readily burned. The vertical extensions serve to prevent the cinders and straw from being drawn into the flames by the draft, and in order to make them more effective, the inventor ordinarily employs stationary water pipes or tubes, which connect with the boiler and extend forward. These tubes will then serve as cleaning fingers, to clear the straw from between the grate bars every time a fresh charge is introduced. By this arrangement of the grate bars, the draft is preserved and an accumulation of cinders upon the grate-bars prevented. This same arrangement can be applied in place of the ordinary furnace door by connecting the inner end of the inclined door with the front ends of the suspended grate, by means of a rod connection extending down to the bars, in which case it can be used for feeding wood brush or other light fuel; or a vertically sliding door can be connected with the grate, so as to be closed by its weighted rear end.

CLEANING COMPOUND.—Margaret N. Cross, San Francisco. This invention relates to an improved compound for cleaning articles of gold, silver, and all polished surfaces of metal; also glass, marble and other substances. It consists in a combination of materials and a method of compounding them, so that the effect is produced of removing greasy or oily matter with a thorough polishing of the surface. In this compound that impalpability of the solid portions is secured which is so essential in any substance which is employed to clean polished surfaces.

SAW MILLS FOR THE BLACK HILLS.—Mechinaw for three complete saw mills has been shipped from a manufactory in Erie, Pa., to the Black Hills during the past month.

(Continued from Page 225.)

end of the bar, *d*, and to the outer end of this arm is fixed a swivel block, *4*, to which a tow strap is secured. This arm can be fixed at the desired position by a set screw, *e*.

When the body of the patient has been adjusted in the bed the sliding bar, *b*, is drawn out until the heel of the foot rests against the heel post. The sliding arm, *3*, is then moved to the proper place, to allow the ball of the toe to rest upon the block, *4*, and the strap is drawn around the foot and buckled, thus keeping the foot in proper position to prevent eversion without any rigid fastenings. The bar, *b*, will slide easily into its socket, in line with the leg of the patient, so that it can be moved longitudinally, but be prevented from moving laterally.

At the foot end of the measuring bar is constructed a drop bar, *7*, which is parallel with the bar, *S*, and attached rigidly to it at each end. This drop bar will come midway between the feet of the patient. A try-square is then used for determining whether the feet are in proper position or not, by placing one arm of the square upon the drop bar, *7*,—first upon one side and then upon the other—so that the opposite arm will stand at right angles to the bar, and thus give the exact measurement.

When the patient has been thus adjusted and his position fixed, if the fracture is of a leg bone, the well leg is attached by means of bandages, with one of the studs, *r*, on the sliding top, *m*, of the box, *Z*, which is in line with the foot. Weights of any kind are then placed in the bucket, *P*, of the box, until the leg is extended to its utmost. The square is then employed for the purpose of measuring the extension. The well leg is then released and the fractured limb is connected with the sliding top of its proper box, and the bucket of this box is weighted so as to extend the fractured limb until it is equal in length to the greatest extension of the well limb.

The counter extension is obtained by the foot of the bed being elevated so as to cause the weight of the patient to counterbalance the weight in the bucket. To do this, feet, *f*, are screwed into legs *B*, of the bed, so that by turning the screws the proper inclination can be given to the bed.

If the bandage on the limb becomes irksome, its position can be shifted by securing a second bandage in another place, and connecting it with two rear studs, *r*, which is made larger than the front one, to permit of the bandage being attached to it without interfering with the front stud. This is a very important point, as when this second bandage is properly adjusted the first one can be removed, thus changing the location of the bandage to the relief of the patient, but without in the slightest degree disturbing the extension of the limb.

In summing up the special advantages of this apparatus we can do no better than to quote the words of Dr. G. W. Dutton, of Tomales, who has used it in his practice, and writes a letter to the inventor, from which we make the following extracts: I have no hesitation in saying that it is the only thing of its kind that has a perfect adaptation to the treatment of fracture of the femur, according to the advanced principles which should be applied in the treatment of this lesion. These advanced principles are:

1st. Extension by weight and pulley; for the reason that the weight is always ready to take advantage of any stretching of the material intervening between the weight and injured limb, and of any relaxation of muscles which may have been in a spasmodic condition at the so called "setting" of the limb.

2d. Counter extension by the weight of the patient's body, applied by means of raising the foot of the bed; for the reason that the continuance of the "pe-inel band" (as in the ordinary method of treating these fractures), when tight enough to be of any use, produces pain and excoriation.

3d. The extension of the sound limb for a criterion in measurement; for the reason that in making the extension of the broken limb the ligaments of the knee and hip joints stretch before the muscles, in a spasmodic condition, allowing the broken bone to extend to its proper place; and if the broken limb is drawn out no farther than until it measures exactly what the sound limb does, without extension, there will yet remain a lapping of the fragments of broken bone.

4th. Measurement with an instrument by which the body of the patient is accurately straightened, and the same point on both sides of the pelvis placed equi-distant from the mesial line; for, in measuring with the tape (now the ordinary way), the surgeon guesses at the straightness of the patient's body and the squareness of the pelvis, and he is very likely to be incorrect.

Your arrangement for supporting the foot, and thereby, in some measure, preventing eversion, and for sustaining the weight of the clothes, and your arrangement for the evacuation of the bowels without soiling the mattress are, it would seem, perfect.

I also notice with admiration your ingenious method of changing the point of attachment of the extension on the injured limb, by which, during the time of such changing, the steady, even, continuous extension is preserved. This novel device will be of use in every ordinary case, in applying the adhesive strips and bandages.

The ease with which your bed can be transported, on account of its compactness, and of its fitting inside the carriage box of a spring wagon is of great advantage.

Sulpho-Carbonate Treatment of Vines.

A paragraph has recently been going the rounds of the press to the effect that the French had found an effective antidote for the ravages of the phylloxera among the grapevines, in the application to their roots of alkaline sulpho-carbonates. Our engraver has reproduced an illustration from an European publication, which was originally taken from photographs of two vines—one of which was treated with the remedy, the other left to the destroying insect.

The useful application to the cure of the attacked vines requires, first, that all the infested surface be treated; second, that the toxic action may be carried sufficiently deep in order to reach all the phylloxera. These two conditions combine for the complete destruction of the parasite. The best means of obtaining a perfect diffusion of the poison in the soil consists in the use of water as a vehicle. The quantity of water employed may depend upon the degree of humidity of the earth and upon expected rains; but the use of some water is necessary. From experiments conducted in France it appears that, to apply the sulpho-carbonate solution, square excavations should be made in the soil, about three inches deep and 30 inches wide. As all the infested locality must be treated, these holes should be made sufficiently near together that the earth partitioned between them shall become soaked after the liquid is poured in. The bottom of the excavation, it is hardly necessary to state, should

EFFECT OF SULPHO-CARBONATES ON VINES.

be horizontal, so as to afford the best opportunity for the solution to infiltrate uniformly into the earth; and this should be borne in mind when the natural level is inclined. The holes should be brought up close to the base of the vine treated. The above done, about two and two-third ounces of the sulpho-carbonate, at 40 degs. B., is mingled with any quantity of water, in the ordinary watering pot or other vessel, thoroughly mixed, and the whole poured into one hole. Repeat this for every hole made, the area covered by the whole number of excavations of course being that underlain by the roots of the vine. Then return the earth about the base of the vine and pour on plenty of fresh water, so that the poison will be forced deep down to the roots.

Our Illustration

Is to give an idea of the practical results of this treatment. The two feet of vines shown formed part of a single attacked part, in which the parasite had existed for three years, and they had reached about the last stage of the disease. In March, 1875, one-half of the selected group was treated with the chemical, the other left to its fate. In the treated portion it should be noted that, out of 260 vines, 60 were already dead. Up to July the vegetation of the vines, without growing any weaker, had not improved; and it was not until the beginning of August that the leaves began to grow green and the shoots to elongate. Meanwhile, the vines not treated were daily perishing. In October, two average vines, one from each portion, were selected and reproduced, as stated, by photography, for the purpose of the present illustration. The vine on the left has very short branches, and its radicular system is almost destroyed; it may be considered, in fact, as dead. That on the right, which was in similar condition to the other before treatment, is evidently considerably improved, new shoots appearing and new roots being thrown out, so that it may be predicted that by next year it will have regained its former vigor.

Our Reporter Abroad.

Dutch Flat.

The charm of mystery which attends quartz mining attracts to it usually more attention than is given to hydraulic mining, which is almost entirely on the surface and in sight, but the ingenuity of the appliances and the magnitude of the operations at this place cannot fail to interest. It has become, owing to the improvements in the process, comparatively easy to wash away entirely the immense channels of gravel and rock from which the surface earth was long since removed by the older and incomplete methods, and mines of wealth denied to the earlier workers are brought now within easy reach.

No mining section in this State has a more assured future than this. The work to be done is plainly in sight and the means of doing it accurately calculated and well controlled. Ultimately, the gravel deposits will of course be washed off to the bedrock, but hardly in 50 years to come. Hence, Dutch Flat looks ahead with much complacency to a long continued period of prosperity. Almost all the companies and firms at work here are under the management of men who are experienced in this kind of mining, and seem to have ample

he surplus, and one, the Yuba ditch company, does no mining at this point.

The Cedar Creek is an English company, under the management of Col. T. B. Lindrum, and is the pioneer of deep hydraulic mining. They own about thirty claims, some of which are in the Gold Run district, and are washing now at five different places, using about 4,000 inches of water. A long tunnel, about 3,000 feet, is projected, and a large part of it completed and now in use. This tunnel is intended to reach the whole of the company's claims in its vicinity, and will be entered through four different shafts. Their Burleigh drill is driven by water (which is the only motive power used by this company), and works its way with great rapidity through an exceedingly hard trap rock. About 60 miles of ditch brings water from the American river and its tributaries for their own use and for sale to other companies.

The Franklin company, of which Mr. James Tesf is superintendent, is washing at present about five hours a day. Their shaft is yet 60 feet in gravel and about the same distance through the bedrock. A stratum of hard clay impedes the work just now, compelling great caution that the sluices and shaft may not be filled in with this tenacious material. Much hard work is required to put it in shape to be washed off. This company owns no water and is supplied by the Cedar Creek company.

Mr. John S. Colgrove has the management of the Polar Star, which is a consolidation of a good many original claims. They are now just ready to wash through one tunnel of about 600 feet, and have a longer one approaching completion. The tunnels are run by contract for them by the Gold Run ditch and mining company, which method they preferred to purchasing the drilling machinery. Instead of the usual wooden blocks used for that purpose, the rille in the tunnel has been laid with old railroad iron and filled in with rock. This is an original idea of the superintendent, and is of course experimental, but he and others seem to have no doubt of its success. At the mouth of the tunnel, a grizzly also made with railroad iron has sufficient incline to carry off all the large boulders, while the water with all the smaller material falls through the bars into a box and goes thence into the flume. The large pieces as well as all the tailings are discharged into Bear river canon at a point 350 feet above the bed of the river, thus providing ample room for the accumulations of years. The company will probably be working through their second tunnel by July 1st. Their supply of water comes from the Yuba company's ditch and will be ample as soon as some breaks are repaired that were caused by recent snow slides.

At Gold Run.

The Gold Run ditch and mining company, Mr. J. L. Gould, superintendent, are washing at two points in their large claim, with a good supply of water. Their water comes from the Yuba and Bear rivers, and is used altogether in their own mines. They expect to have a liberal supply of water this season, as do all the ditch companies, from the unusually large quantity of snow in the mountains. This company was the first to introduce the Burleigh drill into this section, and besides running long tunnels in their own claim, have contracts to tunnel for others. Their main tunnel and branches aggregate over 2,000 feet. A branch connects their main tunnel with the Gold Run hydraulic company's claim, who consequently have the same outlet. The last named is an English company, under the management of Mr. James Stone. Their washing was stopped on the 24th by a closing up of the shaft, but they think the obstacles can be readily removed and that they will resume in a few days.

The claim of Messrs. Hoskins in this district is also temporarily out of water on account of the break in the Yuba ditch, but are daily expecting to be under way.

The Cement mill company is the only other company now at work in the Gold Run district. Theirs is not hydraulic mining, but consists in drifting into the hard stratum and treating this deposit in an eight-stamp mill run by water power. Of course all the deposit above the cement is left, and as portions of it are rich in gold it will inevitably be washed away at some future time by the hydraulic process.

At Dutch Flat, the claims worked by Messrs. Staples, Mr. B. Huysink and Mr. J. H. Decamp, are not the property of incorporations, but are owned and operated by themselves. The Messrs. Towle Bros., who conduct a large business in lumber, have their office and headquarters here, though their nearest mill is several miles distant, and their shipping point farther west. The annual product of their mills is from 10,000,000 to 12,000,000 feet, three-fourths of which finds a market over the mountains, some going as far east as Salt Lake. A railway connects all their mills with the planing mills and the shipping point. An ingenious and successful device has been adopted by them for getting logs up the precipitous mountain sides. A railway track is constructed upon which loaded cars are drawn up the incline, sometimes at an angle of 22 degrees, by a stationary engine at the summit. The wire rope which makes the attachment to the car is wound around a drum 16 feet long, and an adjustable feed, which is an invention of their own, distributes it equally along the drum, so that there is no friction of one coil of rope against another. The track on the incline has the same gauge as their main railway, and thus the cars may be forwarded without unloading to their destination.

Dutch Flat, Mar. 31st.

Persons engaged in the following business can have their Signs Painted at contract prices, for goods or articles in which they trade, viz:

Merchant Tailors,	Gents' Furnish'g G'ds,
Bootmakers,	Furniture Dealers,
Hatters,	Jewelers,
Hotels,	Piano Fortes,
	Wine Merchants. Etc., Etc.

BLAKE'S PATENT STEAM PUMP

Over 8,500 in Successful Use in the United
States.

ENRIGHT'S PATENT PORTABLE

Wood and Straw-Burning Engines.

Patented July 20th and November 2d. 1875

Burns Wood or Straw without change, and Coal by changing two plates. Took the Pre-
minm at the California State Fair, 1875, as the Best Straw-Burner.

Pioneer Builder of the First Portable Thresher Engine on
the Pacific Coast, 1861.

PATENTEE AND BUILDER

OF THE

Best Portable Straw or Wood Burning Thresher Engines, 1876.

Send for Testimonials and Price to

JOSEPH ENRIGHT, San Jose, Cal.

SHERIFF'S OFFICE, SACRAMENTO, Sept. 21, 1875.

Mr J. ENRIGHT—Dear Sir: The Straw Burning Engine I bought of you, and which was
used in Yolo County, has given us perfect satisfaction. It is everything you represented.
We have had no difficulty in generating all the steam required, and the amount of straw con-
sumed can hardly be missed. We find it much easier, on account of fire, than a wood-
burner. Many persons, both threshers and farmers, have come to see it run, and all express
themselves highly pleased. The opinion of all was, that it is just what we need, being safe
and economical.

H. M. LARGE.

AUTOMATIC PUMP.

Raises water by compressed air to any height or distance.
Windmill can be set at any distance from the
well or spring if required to get a good
exposure to the wind.

SEND FOR CIRCULAR.

N. B.—Also manufacturer of Hooker's Deep Well and Double-Acting Force Pump. Received the Silver
Medal awarded at the last Mechanics' Fair in San Francisco.

SUTTER CREEK, February 26th, 1875.

MESSRS. DEWEY & Co.—I have received my Letters
Patent through your Agency. and, for your prompt
ness, accept my thanks. Yours,
S. N. KNIGHT.

THE MINING AND SCIENTIFIC PRESS is one the best
papers published on this coast. It should be in the
hands of every miner and mechanic in the State. The
issue of last week contained an excellent article on the
old product of this coast.—Oroville Mercury, Jan. 28.

[Continued from page 230.]

Utah.

THE TUCUMSEH.—Cor. Salt Lake Tribune, April 1: The Tucumseh is the location on Silver flat which has caused great excitement by the discovery of rich chloride ore. Thirteen tons and a half were shipped to Salt Lake in January, yielding \$440. The last shipment of 20 tons yielded from \$350 to \$750 per ton. This mine is owned by Judge Barbee and others.

THE BRONZA is situated 1,200 feet from the Tucumseh, and is the oldest location in Silver flat. The owners are engaged in stripping the ore, which shows assays from \$50 to \$500 in silver. They have shipped several tons to Salt Lake for a test of the sample value. The mine is owned by Forsyth & Robinson.

THE BRONZA is situated across the first ridge opposite Silver flat. They are engaged in stripping 30 feet on a body of ore showing considerable black sulphurates and chloride, assaying \$158 in silver, several tons of which are now on the dumps. Owned by Jos. Cochins & Co.

Idaho.

GOOD NEWS FROM THE POORMAN.—Idaho Avalanche, March 25: Superintendent Blodgett is now taking out a splendid quality of ore between the third and fourth level in the Poorman mine, south of the shaft. They have also struck a streak of rich ore in the cross-cut running east from the seventh level drift, at a point 350 feet north of the shaft, with flattering indications of soon tapping the main ledge directly under the fabulously rich deposit of ore worked out near the surface in early days.

ALTUS COUNTY MINES.—Our regular correspondent at Rocky Bar writes us that George P. Newton, on the 16th inst. brought over \$514 pounds out of specimen rock taken from this Last Chance mine. There was also taken out six tons of ore worth \$200 per ton, making about \$1,800 in all, realized from the work of three men in less than a month.

General News Items.

PREPARATIONS are rapidly being made for the Belknap impeachment trial.

THE present eruption of Mt. Vesuvius is said to be exceedingly grand.

FRANCE will interpose to relieve the financial embarrassment of the Khedive.

GILMORE will conduct the Centennial musical exercises on the 4th of July, at Philadelphia.

It is stated that Winslow, the Boston forger, will not be surrendered by the British Government.

JAPAN having ratified the postal agreement with the Government, it has now gone into effect.

THERE is a dead-lock between the Plymouth Committee and Henry C. Bowen, which it will be hard to break.

GREAT excitement exists in Kentucky over the discovery of gold on the farm of General Blackwell, in Clark county.

PRESIDENT GRANT is confined to his room and receives no visitors, though he is not confined to his bed. His sickness is periodical neuralgia.

THE House Committee on Public Lands will probably send a sub-committee to California after the present session of Congress, to inquire into alleged frauds in the California land office.

A SPECIAL from Washington says President Grant has sold his property known as Rhode Island farm, for which he paid over \$22,000, and on which he intended building a substantial residence this year. Having become disgusted with Washington life he will probably settle on his home near St. Louis. He is especially anxious to escape from hollow hearted Washington society.

THE River and Harbor Appropriation bill in Congress, reported to the House Monday by Hersford of West Virginia, appropriates in all the sum of \$5,872,850. Among the items are the following for the Pacific coast: Lower Willamette and Columbia rivers, \$15,000; Upper Columbia, including Snake river, \$10,000; breakwater at Wilmington, \$30,000; Sacramento and Feather rivers, \$100,000; Oakland harbor, \$75,000; San Joaquin river, below Stockton, \$20,000; Monterey harbor, \$12,000.

THE Canadian Government have announced their policy respecting the Pacific railroad, which is to ignore the 10 years limit and build it as rapidly as the circumstances will permit. The line has been located from the Lake of the Woods across Red river, via Fort Petty and Edmonton, through the Jasper House pass to Fort George, in British Columbia. The difficulty is to decide out the route from Fort George to the Pacific Coast, 300 miles. The Fraser river route has been abandoned as impracticable, so either the Butte inlet, 150 miles, or more likely Dean channel, 250 miles north of Victoria, on the Pacific Coast, will be adopted as the western end. At the eastern end it is not at all probable that any attempt will be made to construct the section from Lake Nepigon, north of Lake Superior and Lake Huron, to Nipissing for many years, so it may be looked on as practically abandoned, unless there be a change of government at the next general election in two years from now.

HOOVER MINE.—M. E. Ward, who is engaged in the stock business and has an extensive ranch at Granite Creek Meadows, near the Honey Lake road, informs us that a mining company has been vigorously prosecuting work for some time past on the Hoover ledge, which is situated in the Nightingill range, about 15 miles from the Hot springs, on the Honey Lake road. Mr. Ward says the prospects for developing a good mine are very flattering. Three shifts of men are employed in sinking on the lead, in which there is considerable ore of a high grade. Although several silver hearing leads have been discovered at different times in that section of Humboldt county, the Hoover company is the first to make a systematized effort to develop any of them, and it is sincerely hoped that it will be successful.—Silver State.

PATENTS & INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

FROM OFFICIAL REPORTS FOR THE MINING AND SOLE TITIO PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.

By Special Dispatch. Dated Washington, D. C., April 4th, 1876.

FOR WEEK ENDING MARCH 21st, 1876.*

SEWING CASES.—Böhrt Philip and Louise A. Philip, Sacramento, Cal.

REISSUE.

SEWING MACHINE.—Eugens Moreau, S. F., Cal.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue. NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

THOUGHTLESSNESS.—Persons sometimes return their paper, marked "stop this paper." Their name being pasted on the sheet they think that is all we need to be able to cross their names off. Now that is thoughtlessness. Your P. O. address is needed as much as your name. We have thousands of names arranged only according to locality. Our mailing clerk does not know where everybody lives.

BE MORE PARTICULAR.—We can only make the changes requested by the following parties on our mail list, when they, or some one else, send us their P. O. address. Otherwise we would have to look over from 1,000 to 10,000 names. Frank Becker, O. Seawell, L. Boyer, M. Levie, E. Anson and Antonis Byros. We also want the address of Wm. Buck.

UNKNOWN.—We have lately received cash at this office without due explanation, as follows: From Carson, Nev., \$4, by express.

The senders will please give full address, date of sending, etc.

CHOICE VOLUMES.—We have a full new set of Scribner's Monthly—ten volumes—well bound, for sale at this office. Price, \$2 per volume.

WOODWARD'S OARDBNS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menageris, Seal Ponds and Skating Rink.

SEWING MACHINES.—We have a first-class machine which to dispose of on favorable terms. Apply at this office.

Persons interested in incorporated shares will do well to recommend the publication of this official notice of their companies in this paper, as this cheaply appropriates medium for the same.

Eureka Stone Manufacturing Company—

Location of principal place of business, city and county of San Francisco, State of California. Notice is hereby given that at a meeting of the Board of Directors held on the eighteenth day of March, 1876, an assessment, (No. 4) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 557 Market street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fourth day of April, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before will be sold on the eighth day of May, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

P. D. MOWELL, Secretary.

Office, No. 557 Market street, San Francisco, Cal.

The Golden Sun Gold Mining Company.

Location of principal place of business, San Francisco, Cal. Location of works, Forks of Butte Mining District, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 1), levied on the first day of March, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Josephine Gravel Mining Company—

Location of principal place of business, San Francisco, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the twenty-third day of February, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

WM. SMALL, Secretary.
Office, Room 2½, No. 635 California Street, San Francisco, Cal.

Spring Valley District.

The *Coso Mining News* says: This district is situated 25 miles east of Big Pine, in the northern portion of this county, on the east side of the Inyo range, the same range in which Cerro Gordo is situated. The district was some 13 or 14 years ago known as the White Mountain district. The name was changed in 1869 to that of Deep Spring Valley district. A large number of locations have been made since its formation, and a five-stamp mill was erected for working the ores in 1859, but the parties erecting and running the mill knew very little of the proper method of treating ores, and, of course, the mill was shut down. Indian troubles also were another cause of its suspension. From this time up to 1871-72, very little had been done in the district, either by millmen or prospectors, except by Messrs. Hiskey & Walker, who undertook to run the same mill, and these parties made it pay very well, considering the capacity of the mill. Most of the miners then engaged were Mexicans. Becoming involved in litigation with parties in San Francisco, and the Lida valley excitement springing up about this time, Messrs. Hiskey & Walker abandoned their mill at Deep Spring and went over to Lida. Since this time nothing has been done except by prospectors, and some considerable work having been performed on the Golden Treasure mine, by Mr. P. Harrington. This is on a gold-bearing vein of some eight to 12 feet in width, and cropping out holdly for a distance of 4,000 feet. The formation is in slate and porphyry, the slate being on the east and the porphyry on the west side of the vein. A shaft has been sunk to a depth of 80 feet and has been well timbered. At the point where the shaft is sunk the vein was about four feet on the surface, but at the bottom of the shaft it is shown to be eight feet. A number of tons of the ore were taken from this mine to Aurora, at the time that camp was in its glory, and by free milling process yielded \$45 per ton, but after assorting and roasting by the old cordwood process, it yielded at the rate of \$250 per ton in gold, with a small percentage of silver. The mine promises to turn out well indeed, and it is now in the hands of parties who intend to ascertain its value. We shall watch with much interest the development of this mine in particular, as, from actual observation, we believe good mines will yet be found in the northern portion of this country.

LEVI STRAUSS & CO.,

Patent Riveted

Clothing,

14 & 16 Battery St.,
San Francisco,

These goods are specially adapted for the use of FARMERS, MECHANICS, MINERS, and WORKING MEN in general. They are manufactured of the Best Material, and in a Superior Manner. A trial will convince everybody of this fact.

Patented May 12, 1873.
USE NO OTHER, AND INQUIRE FOR THESE GOODS ONLY. eow-bp

WATER TANKS of any capacity, made entirely by machinery. Material the best in use; construction not excelled. Attention, dispatch, satisfaction. Cost less than elsewhere.

WELLS, RUSSELL & CO.,

GOLD MEDAL

AWARDED TO

San Francisco Steam Pumps.

AFTER ONE OF THE
MOST THOROUGH TRIALS

Ever Had in the United States,
BETWEEN COMPETITORS

Best Established Reputation,

In which, at great expense, the different Steam Pumps were tried under every test known to experts, the Examining Committee of the Tenth Industrial Fair of the Mechanics' Institute have awarded to us their

GOLD MEDAL

Best Steam Pumps on Exhibition.

We are prepared to furnish PUMPS UNDER CONTRACT, guaranteeing their ability to perform any specific work for which steam pumps are adaptable, such as

RAISING WATER FROM MINES,

FOR WATER WORKS,

FEEDING BOILERS, RAISING WATER FROM WELLS; STEAMER AND SHIP PUMPS, ETC.

We would also call the attention of those interested, to our Direct Acting Deep-Well Pumps for raising water from

Any Desired Depth.

Also to our Especial Construction of Pumps FOR HANDLING QUICKSILVER or heavy liquids.

We claim that our Pumps are the best ever made in simplicity of construction, economical use of power, durability and perfect adaptability for general uses, and we ask all persons interested to investigate our title to this claim. Salesrooms at our Machine Shop, 114 and 116 BEALE STREET, SAN FRANCISCO.

W. C. WILCOX & CO., Proprietors.

PHILADELPHIA.

DRILLING MACHINES.

PORTABLE DRILLS. Driven by power in any direction, self-feed and convenient adjustment.
RADIAL DRILLS. Self-feed—large adjustable box table—separate base plate, every convenience.
VERTICAL DRILLS. Self-feeding—of new and improved designs.
MULTIPLE DRILLS. For hoiler work, etc., 2 to 20 spindles, fed and returned by power or hand, together or separately.
HORIZONTAL BORING AND DRILLING MACHINES. For large pieces—with boring head, adjustable, vertically and horizontally.
SPECIAL DRILLS. For special work. Gun Blank Drills, Coal Drills, &c, built to order.

HENDY & COCHRANE'S ORE-FEEDER, FOR QUARTZ MILLS.

It is confidently believed to be the ne plus ultra of ore-feeders. One of these machines, on exhibition at the late Mechanics' fair, received the premium over all competing feeders. One was recently set up at Schnabel's mill in Newcastle, Placer county, Cal. It very soon showed itself to be the thing wanted; all other feeders under examination were at once rejected, and three more ordered for the same mill. We refer to the following mills using the Cochrane feeders: St. Patrick, Pugh, Green, and Julian, Newcastle, Placer county. Keystone Con. M. Co., Lincoln and Oneida mill, Sutter Creek, Amador county. Tyho Con. M. Co., Nev.
For description send for circular. **J. HENDY, 32 Fremont Street, San Francisco, Cal.,** where it can be seen in operation. Also, manufacturer of Hendy's Improved Amalgamator and Concentrator and dealer in Quartz Mill Machinery and Machinists' Tools.

Mining Superintendent.

E. B. Smith, for nearly twenty years engaged in the direction of mines and mining enterprises, can be engaged to take charge of any legitimate mining enterprise. Mr. Smith thoroughly understands the "Sonora" process of chlorination and lixiviation, being the originator of the same, and the erection of all machinery and furnaces for the treatment of rebellious ores.

\$400 bush corn ground in 10 hours in 18 inch out weight 500 lbs.
Manufactured by Edward Harrison New Haven, Ct.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

The Pacific Coast and Other Mines Compared.

It was a singular coincidence that the discovery of extensive gold mines in California and Australia were so nearly coincident. During the last 25 years these two localities have contributed nearly equal amounts of gold to that leading specie basis of the world's commercial enterprise, but counting California and Nevada together, these two States have yielded considerably more than Australia. The country next in importance to the two mentioned is Russia, which derives its gold from two localities—the Ural mountains on the west of Siberia, and an extensive district in the southern central portion of the same territory. The average annual yield of the Ural mines is about \$2,500,000, while from other portions of Siberia not less than \$18,000,000 were annually derived during the seven or eight years subsequent to 1846. The island of Borneo is set down as yielding about \$5,000,000 annually. Japan in the height of the Dutch trade with that country is said to have exported about \$250,000,000 in 60 years. Its export has since greatly fallen off. Africa, though supposed to be one of the richest gold countries in the world, furnishes for export an annual average of only about \$7,000,000 or \$8,000,000. South America, with its mines in Chile, Peru, Brazil and Bolivia, was once one of the largest gold producing countries in the world; but of late years it has fallen among those of the least importance in this respect. Gold is found in almost every part of Europe, but in small quantities only. The Hertz mountains in Germany, among which the famous mining city of Freiberg is located, is one of the most important gold producing localities on that continent, and still these mines were over 300 years in yielding about \$60,000,000. The annual yield of the Southern States of our own country is only about \$1,000,000.

Until the development of the Comstock lode in Nevada, Mexico was the largest silver producing country on the globe. The *veta madre*, of all the Mexican lodes, probably approximates nearest to the Comstock in its yield of this metal. It also possesses many similar characteristics in regard to its formation, but it is more uniform in its yield, and in average richness is probably far inferior. The mines on that lode have been worked almost continuously for over 300 years, and yet its aggregate yield has not much, if any, exceeded \$300,000,000, while the Comstock has yielded more than half that amount during the last ten years.

The silver mines of Chihuahua are probably the richest in the world in bonanza, although no one has yet been discovered which has yielded such an immense aggregate as the actual and prospective present Comstock bonanza. The most remarkable bonanza body of ore yet worked in Mexico or in any other locality outside of the Comstock lode, was developed in the Chihuahua district of Mexico, the yield of

which has been estimated as high as \$50,000,000. It was 18 years in the process of extraction, by the slow, clumsy mode of Mexican mining; but might no doubt have been worked out in two years or less, under the energetic management and superior appliances now in vogue on the Comstock.

Some idea of the richness of the bonanza of Chihuahua may be formed from the fact that the first-class ore from these deposits yields all the way from fifteen to twenty thousand dollars per ton, while second-class is set down at a yield of from three to fifteen thousand dollars. The Comstock has nothing to equal this—the average of her present bonanza being two hundred—although there are large amounts of rich chlorides which might be selected that would reach thousands of dollars per ton value. The

half the precious metal deposits of the world; while they will be able to put in circulation and use nine-tenths of the annual increase of those metals. With such a prospect in view the mind is almost bewildered with the great future of wealth before us. The European balance of trade is now but slightly against us, and there can be no doubt that within a year or two the balance must be in our favor. When that time comes the accumulation of specie and other wealth in this country must be at a rate which will bear no comparison with anything in the previous history of nations.

Arizona Ores for the Centennial.

Arizona has made arrangements to secure a suitable representation of her mineral resources

Fig. 1.

MANES' NEW REVOLVING FURNACE FOR TREATING ORES, ETC.

Comstock has yielded more silver in the same space of time than any other known lode, and it is to-day, by far the richest mine in the world.

Immense as has been the yield of the Nevada mines, there is no reason to believe that we have, as yet, more than merely commenced their exploration. There is good reason to believe that many other mines will yet be developed in that State, if not of equal richness, at least closely approximating in value to the Comstock. Utah is also yearly improving in her yield of the precious metals; while New Mexico and Arizona are as yet scarcely prospected. All through an immense territory, embracing some 12 degrees of latitude by as many of longitude—outside of California—we have a region known to be most exceptionally rich in the precious metals.

Moreover, manifest destiny points inevitably to the early acquisition by the United States of the two northern provinces of Mexico—Sonora and Chihuahua—which cover the continuation of this rich mineral belt some four or five degrees still further south, and which are possibly still richer than the region already in the Union. With those provinces in our possession it is safe to say that the United States will hold

at the Centennial exposition at Philadelphia. The last legislature of that Territory made an appropriation of \$5,000 to carry out such an enterprise, but through some lack of attention on the part of those who should have taken the necessary steps to make the same available, the appropriation lapsed, and now through one of her enterprising citizens, Mr. Thomas Ewing, seconded by Gov. McCormick and the mine owners generally in Arizona, the exhibition will be made at private expense. The ores have already been shipped, so packed as to secure their arrival at Philadelphia in good condition. The exhibit will represent 22 different mines, and range in value all the way from one hundred to many thousands of dollars to the ton. According to the *Citizen* it would be impossible to convey by description any adequate idea of the beauty and richness of many of these specimens. This, we believe, will be the first general exhibition of Arizona ores ever made in any locality, and will no doubt prove of great advantage in bringing to the knowledge of the world some practical idea of the immensely valuable mineral resources of this distant mining region.

A New Revolving Furnace for Treating Ores, Etc.

Mr. Manes' Process of Handling Refractory Gold and Silver Ores.—First Process.

As a substitute for the various means now employed for removing sulphur, antimony, arsenic and other volatile substances from ores by roasting, and the smelting and reducing of the same in stationary furnaces, we illustrate in this issue an improved revolving furnace, invented by James Manes, of New Haven, Conn.

In this process the ore is first crushed or stamped to a powder and 25 per cent. of fuel and one per cent. of black flux mixed with it. When so treated the powdered ore, to the

amount of one ton or more, is put into the furnace (Fig. 2, which will be found on page 249) through the man-hole, J, which is then closed and the furnace started. The charge thus introduced will be thoroughly desulphurized in one hour or less, and the arsenic or other impurities carried off. The chemically prepared amalgam is next added, which takes up all the precious metals in a very short time. After this the charge may be removed to the settler or washing machine, where all the earthy matter is removed, and the amalgam left ready for retorting, when the work is completed.

For handling refractory and low grades of gold and silver ores, the inventor claims for the apparatus special advantages, as by its use several tons can be worked daily, and the labor of but one man to attend the furnace will be required. The globular form adopted is one easy of construction and well suited to sustain its great weight from two points of support. The lining of the interior can also be rendered more stable than in any other form, while it presents less surface for the radiation of heat.

Second Process.

If gold and silver ores must be smelted they are first desulphurized, the same as in the amalgamating process, and mixed with 20 per cent. of fuel (coke preferred) and one per cent. of red flux. The charge is then placed into the furnace (Fig. 3) through the man-hole, J. The furnace having been previously heated to a dull red color, with 500 pounds of lead at the bottom, it should be kept going at a very gentle blast until the whole is melted. The furnace is then tipped over with the lever wheel until the man-hole, J, is in a horizontal position. The cinder is then skimmed off, 100 pounds of zinc added and mixed thoroughly with the melted mass, and it will take up the gold and silver, which can then be skimmed off and retorted.

Fig. 1 is a perspective view of the apparatus; Fig. 2 a longitudinal section of the furnace as used for roasting ores; and Fig. 3 a transverse section of the invention arranged for smelting purposes. Referring to Fig. 2, A is a sphere of boiler plate or cast iron, lined with gaultier, fire brick, and asbestos, the effect of which lining is to keep the exterior of the sphere cool, even while an extremely high heat is maintained

CORRESPONDENCE.

Botanical Excursions.

[By J. G. LEMMON.]

No. 2.—The Northern Valley and Lassen's Peak. Part 1st. Sierra Valley to American Valley.

"I wish you would explore Lassen's peak again," writes Dr. Gray. "What I have seen from there but sharpens the appetite for more."

Some three years ago I visited Lassen's peak, on one of my first botanical trips. I was accompanied then, for the first time, by the genial gentleman who has so often been my companion since, Prof. E. L. Case. Starting from his then home, in Indian valley, we passed via Greenville, 70 miles, through Big Meadow valley, and, climbed old Lassen, spending 10 days in the exploration, and experiencing many interesting adventures—particularly that of sliding from the monument of Lassen down on the snow, over a half mile in less than a half minute.

We brought home a few plants only in a copy of *Harper's Monthly*, but among them were several new to California, one interesting *Cycladenia*, collected but once before, and a very beautiful, sweet-scented *Corydalis*, entirely new to science. It was perhaps the presence of these plants in the Harvard herbarium that caused Dr. Gray to make the above request.

I had agreed already to make a general collection of Sierra flora for Dr. Vasey, to exhibit at the Centennial, so to go again to Lassen's peak just suited me. Prof. Case being engaged in teaching, I solicited the company of Mr. John Larsen, a young dry-goods clerk, just then out of employ. Larsen was a new hand at mountaineering, but he soon learned to be very efficient in the care of the team and preparation of food, as also in collecting and preparing plants. A strong, and, we trust, life-long friendship is based upon that grand excursion.

We started from Sierra valley, June 18th, 1875, equipped with all the added articles that previous campaigning suggested, and certainly the passer-by could not mistake our business, or think we were going to suffer from hunger or cold on the trip. We knew it would be a grand excursion, for we were to pass through a long chain of the most delightful valleys in all California; and then at the far end of the east towered up Lassen's peak, ever snow-crowned, and commanding a view not only of northern California, but many miles over the border into Oregon.

With hearts elate we set out, and, with the editor's permission, the *RURAL* readers are again invited to accompany. But first let me give you a foretaste, a cursory glimpse of the country, lest you complain of the hardships endured before reaching the lovely scenes.

Prince Sierra and His Jewels.

The Sierra Nevada is a rich, lordly bejeweled prince among mountain ranges.

Reclining in state, like an Oriental monarch, upon the bosom of the great treeless plain of Western America, it is clothed from end to end—600 miles—and from base to base—140 miles—with a dense forest of evergreens, like a royal robe. This enrobing forest—the noblest in North America—is perforated along its center line by a thousand peaks, rising through the royal mantle into the Alpine region of eternal winter, and is rent along both slopes by a million valleys, depressed through the garment into the middle region of the changing seasons.

The peaks are the brilliant diamonds of this wealthy prince; the valleys, the hidden pearls. The former flash upon the voyager in the far Pacific and the Utah desert, but through the emerald setting of the forest must the explorer search for the latter resplendent gems.

Differing from a few acres to 400,000 acres in extent, these valleys floored with alluvial soil and carpeted with meadows, form the true wealth of the Sierra. To be sure the heart of the Sierra is golden, but where one mines into it and becomes a happy millionaire, a thousand dig as deep and become wretched mendicants. The gold first discovered led to the rapid up-building of camps and towns in the high ravines, now fast disappearing. The wealth of the valleys lately developed, is now attracting a population which will ever increase.

To work the mines, their debris must be spread over and ruin the valleys. The voice of fast growing communities is now loudly heard in rightful protest.

Prettiest of all these valleys, and also least affected by mining operations, are those found on the east side of the north end of the Sierra, which region may be taken for the broad breast of Prince Sierra, decorated with these bright jewels.

Five of the largest, arranged in nearly a right line, form center decorations or orders of nobility, surrounded by gems of lesser size and varied lustre, according as they are on the side toward the peaks or toward the plains.

These large valleys, while having a generic character of great fruitfulness, differ in attractions for the visitor, owing to the difference of latitude, origin, elevation, contour, area, population and surroundings. Let me bring these

valleys into one view for comparison of statistics—otherwise dull and valueless. The first on the south, 20 miles from the C. P. R. R., is Sierra valley, drained by the upper streams of the south fork of the Feather river. Latitude, 39½ degs. Elevation, 5,300 feet; contour, a Turkish crescent. Area, 300,000 acres. Population, 2,000. Towns, Sierraville, Randolph, Loyalton and Beckworth. Sentinel peaks, (or crowning diamonds—to continue this figure,) Webber, Haskell, Beckworth and Volcano.

The second, 16 miles northwest, is Mohawk valley, drained by the south fork of the Feather. Elevation, 4,500 feet; shape, a three linked Odd Fellow badge; area, 2,000 acres; population, 400; towns, Jamison and Eureka; peaks, Haskell and Eureka.

The third, 12 miles farther north, is American valley, drained by Spanish creek. Elevation, 3,200 feet; form, a Masonic triangle; area, 8,000 acres; population, 500; town, Quincy; peaks, Clermont, Spanish and Grizzly.

The fourth, 12 miles farther northwest, is Indian valley, drained by the middle fork of the Feather. Elevation, 9,300 feet; form, a four armed Melisse cross; area, 16,000 acres; population, 1,600; towns, Taylorsville, Crescent and Greenville; peaks, Kettle, Huff's and Greenville.

The fifth and last, 12 miles farther northward, is Big Meadow valley, drained by the north fork of the Feather. Latitude, 40½ degs.; elevation, 4,000 feet; contour, a heart shaped shield; area, 400,000 acres; population varying from a few families in winter to 500 souls in summer; town, Prattville; peaks, Keddie's, Black, and the over-towering-Lassen.

Sierra Valley.

In an article, "Sierra Valley and some of its New Flowers," published a year ago in the *RURAL*, I partially described this valley, so we will omit farther words now. While we scamper along the smooth roads northward, through the entire length of its crescent, the reader may look over its level of waving meadows and grain-fields, cross-barred with substantial board fences, and dotted with farm houses; he may gaze across at the heavy pine forest on the west and speculate upon the vast wealth of lumber in those tall, straight stemmed trees, or raise his eyes higher and contemplate the grandeur of the towering encircling peaks; then let him tell me if I exaggerate the beauties and wealth of Sierra valley.

Mohawk Valley.

Following down the south fork of the Feather river, rising in Sierra valley, we enter Mohawk valley on the east side of the middle link of the badge described, or middle valley of Mohawk. In the upper, on the east side is a celebrated sulphur spring, and one of the finest hotels in the mountains. Across the valley are the gravel mines and settlement of Mohawk. On the west side of the middle link, boring into the heart of Eureka peak, are the long tunnels of the Plumas Eureka quartz mine, the richest deposit of gold yet developed in the Sierra. Always paying increasing dividends, a few years ago it passed into the hands of an English company, the same that owns the Sierra Buttes mines and several others—who built mills, employed a large force of men, and now realize tenfold more profit annually. A new town, Eureka, grew up at the mouth of the tunnels, and a large and constant demand for the products of the valleys far and near. A tri-weekly freight and express plys between Eureka and Truckee, crossing Sierra valley, and a semi-weekly stage connects northward to Quincy and beyond.

On the east side of the lower link, or Teft's valley, are the Argentine quartz mines, employing several hands, who are abundantly supplied with food from the rich vegetable gardens of the valley.

Each of these little valleys and the open woods adjoining are studded with rare mountain flora, particularly the sweet Washington lily and the modest *Fritillaria recurva* and *pudica*. In Culver's orchard, in the settlement of Mohawk, by the upper valley, grows a new species—or at least a very remarkable variety—of violet, resembling in flower the *viola lobata*, but the stem is from 10 to 15 inches high and the leaves entire and cordate. In a cool spring and its brook near, grows the new *Corydalis Caseana*, of which, more hereafter.

American Valley.

This beautiful vale is one of the first settled on the eastern slope, owing to the gravel mines on the head waters of Spanish creek, still paying well, and it has been steadily appreciated as a home by a thriving people, who established the largest town and capital of Plumas—Quincy, in its comparatively small enclosure. Quincy has many fine residences and two large hotels necessary to accommodate the throng of summer visitors, that escape annually from the heats of the Sacramento valley.

Larsen and I were most hospitably entertained during our exploration of American valley and Clermont peak, by Mr. Sam Lee and wife, residing on a fine ranch south of Quincy. On this ranch grows the robust and lately discovered *Eriogonum ursum*, and near it the new *Solanum Zanli*.

Three and a half miles south of Quincy is a rich little valley called "Illinois ranch," owned by Mr. John Thompson, a successful farmer and experienced breeder of fine horses. His Plumas colts are beautiful and serviceable animals, always selling at high prices—some of them away up to a thousand dollars.

Mrs. Thompson is a great lover of flowers and takes the greatest pains and delight in their cultivation. Her gardens, walks, and

conservatories are, by far, the most extensive and finest of any in the mountains. She prizes equally well our native flowers, and has included a large number of them in her fostering care. Mrs. Thompson has a genial friend and co-worker in the person of Mrs. Dr. Cate, residing in Quincy. Among other achievements in the floral line, Mrs. Cate has produced a beautiful white leaved geranium, and has succeeded in bringing the famous *Darlingtonia* into bloom.

At the bare mention of that last plant, a long train of pleasant scenes and incidents comes trooping into mind, connected with Buttersfly valley, one of the attendant gems of American valley, and next to be described. But already this number is long enough for its kind, and we are only half way to Lassen's peak. Varied reading is what gives worth and popularity to a journal like the *RURAL*, so I must not crowd out other contributors, who may have much to say of more interest to the many.

(To be Continued.)

The New Fish Law.

The following is the full text of the act for the protection of the small fish in our waters from destruction by the Mongolian fishermen: An act to amend Section 634, 635 and 636 of the Penal Code.

The people of the State of California, represented in Senate and Assembly, do enact as follows:

Section 1. Section 634 of the Penal Code is hereby amended to read as follows:

Section 634. Every person who, between the first day of August and the first day of November in each year, takes or catches, buys, sells or has in his possession any fresh salmon is guilty of a misdemeanor. Any person catching or having in his possession, or offering for sale, shad at any time prior to the first Monday of December, A. D. 1877, is guilty of a misdemeanor. The following counties are exempted from the provisions of the first section of the bill: Del Norte, Humboldt, Shasta and Mendocino.

Sec. 2. Section 635 of the Penal Code is hereby amended to read as follows:

Section 635. Every person who places or allows to pass into any of the waters of this State any lime, gas, tar, coculus, indious, or any other substance deleterious to fish is guilty of a misdemeanor, and every person who uses any poisonous or explosive substance for the purpose of taking or destroying fish, is guilty of a misdemeanor; provided, that sawdust shall not be deemed a deleterious substance. Any person who shall catch, take or carry away any trout or other fish from any stream, pond or reservoir belonging to any person or corporation, without the consent of the owner thereof, which stream, pond or reservoir has been stocked with fish by hatching therein eggs or spawn, or by placing the same therein, is guilty of a misdemeanor.

Sec. 3. Section 636 of the Penal Code is hereby amended so as to read as follows: Sec. 636. Any person who shall set, use or continue, or who shall assist in setting, or using or continuing any pound, weir, set net, stake net, trap or any other fixed or permanent contrivance for catching fish in any of the waters of this State, is guilty of a misdemeanor; any person who shall hereafter close or keep closed, or in condition to catch or ensnare any shrimp, in any pound, weir, set net, stake net, trap or other fixed or permanent contrivance for catching the same, placed in the waters aforesaid, is guilty of a misdemeanor; any person who shall draw or shall assist in drawing any net or seine for the purpose of taking shrimps in any of the waters of this State, at any time between the setting of the sun on the evening of each Saturday and the rising of the sun on the morning of the succeeding Monday, is guilty of a misdemeanor; any person who shall draw or assist in drawing any net or seine for the purpose of taking fish in any of the waters of this State, the meshes of which are less than one and a half inches in size, is guilty of a misdemeanor; provided, that nets with a mesh of a smaller size may be used in the catching of shrimps; any person who shall cast, extend or set any seine or net of any kind for the catching of fish in any river, stream or slough of this State, which shall extend more than one-third across the width of said river, stream or slough at the time and place of such fishing, is guilty of a misdemeanor; any person who by seines or any other means shall catch any fish so small as to be able to escape through a mesh of one and one-half inches in size or the young of fish of any species, but which at the time of capture are too small to be marketable, and who shall not return the same to the water immediately and alive, or who shall sell or offer for sale any such fish, is guilty of a misdemeanor. One-third of all penalties received under this section shall be paid to the informer, one-third to the District Attorney of the county in which the case is prosecuted, and one-third to the school fund of said county; provided, that nothing in this section shall be construed to affect any special law now in force in this State for the preservation of fish; provided, that in the waters of Carquinez straits and Napa river set nets and stake nets may be set and used of meshes not less than two and one-half inches.

Sec. 4. This act shall take effect and be in force from and after its passage.

ANOTHER FARMER'S RAILWAY.—The farmers of Richland county, Wisconsin, have built a wooden railway, sixteen miles long, costing only three thousand dollars a mile.

Selby Hill Gravel Mining Company.

This company, says the Nevada Transcript, which is composed principally of San Francisco capitalists, a short time ago purchased this ground on Selby hill known as the Downis ground. This claim, as well as many others that adjoin it, has been lying idle for the past fifteen years or more, with the exception of this old Nebraska, now known as the Woodville. When these claims were in active operation there was quite a large settlement at Selby Flat and several hundred men were employed, and after this suspension of work this city felt its effect most severely. There were many causes for the cessation of work there; the principal ones, however, was want of fall to the known rich gravel lead which run through there, and several of the companies having lost the channel. It is estimated that millions of dollars have been taken out of the Nebraska and the adjoining claims at the time they were worked. As we said before, nothing has been done to this ground until now. The Selby Hill gravel mining company, whose ground adjoins the celebrated Nebraska, was incorporated a few weeks since and elected the usual officers, who immediately commenced work by letting a contract to Donnelly, Skehn & Co., to run a tunnel, which, when completed, the company will be able to work the ground to the lowest depths of the gravel. The tunnel is to be run 2,000 feet and will be 5 feet 10 inches in the clear, with timbers 8x8, making it of the most substantial character. They have run a cut about 100 feet to the face of the tunnel, which is on Austin ravine, near the residence of John Dunn, on Selby Flat, and have put in six sets of timbers, and have now encountered some hard blasting rock. Three shifts of men are at work on it night and day, and it is expected that it will take about nine months to complete the job, and by that time the whole claim will be in condition for very extensive work, and give employment to a very large number of men. While this work is going on, the superintendent, John Cashin, is contracting for 2,000 feet of iron pipe, which, when completed and put in, work of washing will be commenced, all of which will be ready in about three weeks. The tunnel is being run to work the heavy ground, while the surface will be worked through the creek. As soon as the pipe is connected with the South Yuba canal company's ditch, which will have a pressure of 280 feet, working will be commenced and carried on night and day, using about 1,000 inches of water per day and giving employment to many miners. A short time ago Mr. Cashin put two men to work on a small piece of this ground, in order to sample it. They worked a while with a small stream of water, in ordinary sluice boxes, and they cleaned up \$90. The ground they worked off could have been done with hydraulic power in an hour, which goes to show that the ground is exceedingly rich. The company have about 70 acres of gravel territory and it will take many years to work it out. The stock of the company has nearly all been taken and a sufficient number of shares for a working capital have been sold, and it is believed that the ground will pay sufficiently in a very short time to pay all the expenses the company have been at.

Mills and Mines About Mineral Park.

A correspondent of the Arizona Miner says: I have deferred writing up Mineral Park for some time, waiting until the Mineral Park mill should be completed and in full operation. The mill, thanks to the energy of R. B. Canfield, superintendent, and the skill of Madison Chase, the boss mechanic, under whose personal supervision the mill in all its parts has been constructed, is complete in all its parts, and is a perfect success. The only thing wanting is a first-class article of fire brick for the ends of the furnace cylinder, which it is believed will be obtained from material now on hand. The mill in all its parts is of the improved and perfect character, and no doubt superior to any other of like capacity on the Pacific coast. It is a 5-stamp mill of 550 pounds each, having 8-inch drop and 90 drops per minute, and crushes with No. 40 screen 10 tons per day. Engine, 10-inch cylinder and 20-inch stroke. The furnace is Bruckner's revolving cylinder with a capacity of 3,000 pounds at each charge; each charge requiring 6 hours. The machinery was built by H. J. Booth & Co., now Prescott, Scott & Co., of San Francisco, Cal. The steam pump—Hooker's No. 3—supplies the boiler and tanks connected with the amalgamating apparatus and the fire hose. The rock is prepared for the stamps by one of Blake's 8x10 rock breakers. A small burr-stone mill is used for crushing salt and sampling ore. The machinery was sent from San Francisco about one year since, but owing to the undeveloped state of the mines the work of construction was deferred until late last fall. It is intended for a general custom mill, for reducing the ores of the Wallapai mining district and surrounding country, and will no doubt exert a wonderful influence in assisting towards the development of hundreds of rich lodes in the country around. The total reducing capacity of the mill is fully equal to the capacity of the stamps. The ores crushed during the few days' work since starting have been from the Keystone mine, a half mile distant, and the Hackberry mine, being the south extension of the Hackberry mine, which is 30 miles east in the Pescoc mountains. The bullion product of the ores worked gives an average of \$200 per ton. The average chlorination of the furnace have exceeded 90 per cent.

SCIENTIFIC PROGRESS.

Evaporation and Percolation.

G. J. Symons, secretary of the British meteorological society, read a paper at the recent session of the Institute of Engineers, giving some very interesting experiments devised to measure the extent of atmospheric evaporation. His statement contained a proposal to gauge, by an apparatus as simple as an ordinary rain gauge, the loss of water from the re-evaporation of rain; the usual method of learning the hygrometric state of the air being by the dry and wet bulb thermometers. The gauge includes a percolation gauge, which was larger but did not differ greatly from the Dalton gauge, started by the late Mr. Dickenson at Abbott's Langley, to which the author had added one filled with fine sand to ascertain maximum percolation. Lastly, evaporation from the surface of water was determined by floating the gauge in a vessel or in some river, open tank or reservoir, and it was assumed that the water in the inner vessel acquired the general conditions of that in the outer vessel. The rain gauge and percolation gauges were not new, but the form employed for determining the amount of evaporation from the surface of water had not been proposed elsewhere; moreover, the four series of observations had never been brought forward in juxtaposition and with apparatus of uniform construction. Tables were submitted of the rainfall from observations uninterruptedly maintained since 1855; of the percolation, which by subtraction showed the evaporation from the ground, since 1855; of the percolation through sand, which furnished also the evaporation from sand, since 1860; and of the evaporation from a surface of water. The author gave the average rainfall as 25 inches, the average percolation through sand as 20 inches, and the evaporation from the surface of sand as five inches; percolation through earth as seven inches; evaporation from the surface of the earth as 18 inches; evaporation from the surface of open water, 20½ inches; and the gain of water in an open tank, four and one-half inches only. These tables showed that all the water that could be relied upon as retained for use was a depth of seven inches, if the rain fell upon a permeable soil, and of four and one-half inches if it fell on an open tank or reservoir. To secure more than this, covered reservoirs or close vessels to prevent evaporation would be necessary. The phenomena of peculiarly dry years—years in which rivers and springs have been deficient, viz., 1861, 1864, 1868, were discussed. Springs and rivers had been redundant in 1852-53, in 1857-58, in 1860, in 1866 and in 1872. It was manifest that with a view to provide for the permanent and continuous needs of large communities, the probable fluctuation of delivery of water in a river might be gathered by watching closely the sequence indicated by the percolation gauge. Heavy rains and storms in summer might produce a river flood, yet fail to replenish the springs; and a long frost, even with considerable snow, might leave rivers and springs very short of water for the following autumn; and a dry winter imperilled the permanence of river discharge more than a hot summer. The latter, however, might succeed a dry winter, under which circumstances the deficiency of water in the rivers must become alarming, in view of the present tendency to the agglomeration of populations. One result of the comparisons deduced from the tables attached to the paper was that the storage of water might be more safely and largely secured in a porous subsoil, covered with a turfed surface, than in ponds, reservoirs or other accumulations of open water. The author added that frequent thaws of small falls of snow produced the greatest amount of percolation; that hollow draining did not diminish the perennial flow of rivers; that capillarity had only a negative influence; that the influence of a wet period on percolation rarely extended over more than one season, and was soon obliterated by a dry winter succeeding. The flow of springs and of rivers followed the increase and decrease of percolation more closely than the rainfall, except in the temporary effects which immediately succeeded on copious rains. Negative evaporation, or an increment of water without rain, occasionally, though seldom, occurred in the floating gauge; but it was of frequent occurrence in the sand gauge, from the low temperature acquired by the sand by radiation, when the gauge became a dew tank.

RUSTING OF IRON.—It has generally been supposed that the rusting of iron depends principally upon moisture and oxygen. It would appear, however, from the late Dr. Calvert's experiments, that carbonic acid is the principal agent, and without this the other agencies have very little effect. Iron does not rust at all in dry oxygen, but little in moist oxygen, while it rusts very rapidly in a mixture of moist carbonic acid and oxygen. If a piece of bright iron be placed in water saturated with oxygen, it rusts very little; but if carbonic acid be present, oxidation goes on so fast that a dark precipitate is produced in a very short time. It is said that bright iron placed in a solution of caustic alkali does not rust at all. The inference to be derived is that, by the exclusion of moist carbonic acid from contact with iron, rust can be very rapidly prevented.

Detonation.

The last meeting of the British chemical society was held at Woolwich arsenal, and one of the subjects consisted of experiments on detonation. Of these there were three series. The first showed some of the conditions which promote detonation of an explosive agent by a blow or by the force exerted by an initial detonation. The experiment, however, intended to show that a fuse of mercuric fulminate, strongly confined and exploded in uncompressed gun-cotton, will not detonate it, directly contradicted the programme, and on repetition was equally unsuccessful. The second series illustrated the transmission of detonation, which as ascertained by Noble's chronoscope ranges from 18,000 to 21,000 feet per second. This has been determined by detonating a row of discs 36 feet long, insulated wires being stretched across the row at intervals of six feet; their rupture by the detonation gives spark records on the chronoscope, from the relative position of which the rate of transmission of detonation is calculated. These experiments were very successful. In the last of them 60 grammes of compressed gun-cotton were inserted into one extremity of a wrought iron tube five feet long, the detonation being transmitted to a disc of compressed gun-cotton inserted into the other extremity of the tube. The explosion split up the ends of the tube, breaking off one piece about six inches long, which whizzed through the air with a sharp sound, finally falling not very far from its original position. Various illustrations of the applications of detonation formed the third series. A wrought iron rail was destroyed by a charge of about half a pound of compressed gun-cotton placed upon it and detonated, illustrating the hasty demolition of a line of railway, by cavalry pioneers. A piece of wet gun-cotton, removed from a fire upon which it would not burn, was placed upon a block of granite and there detonated by a small charge of dry gun-cotton. Its effect was to shatter the granite to pieces. A stockade, built up of stakes about a foot thick, was similarly blown into small pieces, a great hole being also excavated in the earth. Finally a submerged charge of wet gun-cotton was detonated in a pool of water, sending a spout high into the air. In this case the charge was open on all sides to the water, being confined round the dry initiative charge only by means of a net.

Salicylic Acid.

Salicylic acid, until recently not found outside of chemical laboratories, is now coming largely into use as an antiseptic and as an agreeable substitute for carbolic acid. We give a variety of new recipes for its employment, taken from various sources: A very simple and most useful ointment, which answers admirably in some affections of the skin, is formed of one-half drachm to a drachm of the acid to seven drachms of simple ointment. A liniment of salicylic acid and olive oil (two drachms of the acid to eight ounces of oil) will be found of much efficacy in burns. Soak lint in the liniment and apply to the suppurating surface. Professor Will, of Aberdeen, who has tested this in some severe cases of burns, commends it strongly in the *Lancet*. For cancerous sores, Thiersch recommends dusting with pure acid, or with equal parts of the powder and starch; or powder formed of charcoal and the acid might be employed for the same purpose, or for dusting over poultices applied to sloughing surfaces. Another ointment is made of sperm oil, one and one-half drachms; oil of theobroma, two and one-half drachms; salicylic acid, from one-half to one drachm. This forms a thick paste, which should be thickly spread on lint. The heat of the surface acting on the oil of theobroma, a diffusible ointment is formed, which is a suitable application when it is desired to have the discharge thoroughly saturated with the antiseptic. An ointment less easily acted on by the body heat consists of sperm oil and paraffine, of each one and one-half drachms; oil of theobroma, two drachms; oil of almonds, one drachm; salicylic acid, from one-half to one drachm.

PHOSPHIDE OF COPPER.—What has been introduced with some éclat as an alloy of copper and phosphorus proves not to be an alloy, but a true chemical combination of copper with phosphorus, or a phosphide of copper in definite proportions. The union of the two may be through the hot or cold process, the cold sufficing for certain applications, being preferable indeed to combinations produced by heat. By the hot process the introduction of simple bodies other than the metals or metalloids is prevented. The copper used in the process must be commercially pure. Of the three kinds of phosphorus the operator may take his choice; the ordinary, the amorphous, and the earthy bi-phosphates. The amorphous is the most expensive, and is also the best. According to Delatol, the percentage of phosphorus varies from two to four, between which there may be an infinity of degrees, although for industrial purposes five varieties meet all the requirements. These are formed with two per cent. of phosphorus, two and a half per cent., three, three and a half and four per cent. Above four phosphor bronze is useless, but between three and four per cent. the material is claimed to be superior to any other metal or alloy.

FARADAY calculated that the decomposition of a single grain of water required 800,000 discharges of his Leyden battery.

MECHANICAL PROGRESS.

Dynamite.

The wide use of dynamite as an explosive renders valuable all careful tests of its qualities and characteristics. The latest issue of *Iron* contains an account of some tests with the explosive, recently made by the British dynamite company, bearing directly on the safe transport of dynamite by rail. In the first test, a 3 cwt. block of iron, being raised to a height of 24 feet, was allowed to fall on a wooden box containing 50 pounds of dynamite. As the result, the box was smashed, and although several of the cartridges were compressed and burst, no explosion ensued. With a view of showing the intense local action of the explosive, 10 pound weight was placed at a distance of nine feet from a temporary wooden fence, and after the explosion it was found that fully one-half of the spar had escaped damage, whereas it was concluded that had an equal quantity of gunpowder been fired the paling would have been entirely destroyed. Though dynamite was knocked about during a collision, the manager expressed his belief that it would not explode, and even should this be the case the area of destruction would be extremely small. In order to prove the effective use of dynamite as a fog signal at sea, experiments of a different kind were made. It could be fired from a spar without the slightest danger either to the spar or to those on deck—as was shown by two cartridges being placed at the end of a fishing-rod, which remained intact—or the same effect would follow if the cartridge were attached to a small piece of wood and thrown into the water. In another experiment a cartridge was sent to the bottom of a pond, the explosion sending up the spray in a column 40 feet in height. With a view to test the effect of an explosion of gunpowder on a box of dynamite, 25 pounds of powder was placed in a hollow, closely covered by a large half-inch iron plate, on the top of which was laid a box containing 10 pounds of dynamite. After the firing of the charge it was found that the plate had been thrown a distance of nine feet, and had smashed the box, without any explosion of dynamite having taken place. Afterwards a wire rope, fully one inch in diameter, was nearly severed by half a pound of the explosive, and this was considered an operation difficult of performance. The final experiment consisted of forcing a circular tin plate through a half-inch iron plate. To effect this two pounds of dynamite was placed in a small wooden roller, open at either end, a tin plate, the exact circumference of the opening, being placed at one end, and the iron plate at a distance of two feet. By the explosion the tin plate was completely smashed, but it had perforated the iron plate, leaving a series of neat circular openings. It was explained that the roller being open at either end the explosive force was diminished by one-half, and that by placing a plate at each end the test could be duplicated. Although numerous other experiments were in preparation, the gentlemen present expressed themselves satisfied with what they had seen.

The Preparation of Dynamite.

Of the composition of the substance tested above we find the following in the *American Chemist*: Of the numerous explosive powders put on the market, dynamite alone appears now to be in demand. Dynamite, containing 75 per cent. of nitro-glycerine, should theoretically have three-fourths the explosive force of that agent. Practically its power is about two-thirds that of nitro-glycerine, probably in consequence of the absorption of heat by the silica. Five hundred kilos of dynamite are used daily in the St. Gothard tunnel. If the rock is very wet, a German preparation called "cellulose dynamite" is used, which does not part mechanically with its nitro-glycerine so readily as the silica. Its mode of preparation is not known. Three classes of absorbents are used for nitro-glycerine. 1, Natural silicious material; 2, Artificially prepared silica; and 3, Some spongy material, to which class the cellulose belongs. Dynamite No. 1 contains 75 per cent. nitro-glycerine; dynamite No. 2 contains a sodic or potassic nitrate powder, with about 40 to 50 per cent. nitro-glycerine; dynamite No. 3 contains still less nitro-glycerine and more of some cheap gunpowder. All three are about equal as regards explosive force. According to Nobel, the best No. 2 contains an ammonia powder and 15 to 20 per cent. of nitro-glycerine, and gives 10 per cent. more explosive power than No. 1 dynamite. In using dynamite, one-third less holes and holes one-fourth less in size than with gunpowder are necessary. The saving from its use is about 30 per cent. No. 1 burns more readily than Nos. 2 or 3.

A NEW ANTI-INCORUSTATOR.—A new anti-incrustator has lately been introduced under the name of apparaline, which is prepared by stirring up 16 parts of potato starch in 76 parts of water, and then adding eight parts of potash or soda lye, at 25 deg. Baume, the whole to be thoroughly mixed together. In a short time the mixture forms a thick jelly, and it is then beaten up vigorously for a time, when it forms a colorless, transparent substance, slightly alkaline to the taste, and of a strong glue-like consistency. It dries slowly in the air, without decomposition, and when perfectly dry resembles horn, but is more flexible. When introduced in small quantity into steam boilers it prevents their incrustation. It is also

capable of nearly all the applications of ordinary gelatine, and is especially adapted for alizing textile goods of all kinds, imparting to them a hitherto unattained smoothness. When once applied to goods and dried it is perfectly insoluble, as three or four washings in hot water have proved to have no effect upon it. It can also be used as a thickening in calico printing. Several of the textile journals speak of this substance as a very important addition to the resources of the manufacturer and dyer. Care must be taken to retain it in air-tight vessels until it is used, as it is not easily rendered soluble again when it once becomes hard.

A Suggestion for the Centennial.

Our London exchange, *Iron*, makes the following suggestion for mechanical progress at the Centennial. It says: The question of the best form for the interior of the blast furnace has not of late years occupied so prominent a place in metallurgical discussions as it deserves. Advantage might be taken of the forthcoming Exhibition at Philadelphia to secure much valuable information, which it would be beyond the power of any individual, or even an association, to obtain at any other time, but which, once collected, would be of the greatest service to metallurgical industry. It is not, even now, too late for the commissioners of England, Germany, France and Austria, in conjunction with the American Centennial authorities, to invite by circular the leading metallurgical firms of their respective countries to furnish, in a specified form, such detailed particulars, illustrated as far as possible by plans, of the working of the plant and processes under their control, as they may feel disposed to give. Such information from reliable sources would at once set at rest many vexed questions, which would otherwise only be tardily solved at an enormous cost of unproductive labor and wasted material. That we ourselves have much to learn from the best Continental and American practice, is not less true than that in many points we are in advance of our neighbors. Not the least important feature in such a programme would be the collection of a series of internal sections of blast furnaces blown out for repairs or other causes (of which there are unfortunately just now only too many). Accompanying these fire-shaped sections would be drawings of the original contour, with full details of the charges used, and the working immediately before the stoppage, and at different periods of the campaign. Such returns would form a solid basis for subsequent progress, and would materially advance that which should be the leading object of a true world show—the growth of technical knowledge. Failing its adoption by official representatives, we commend the idea to such bodies as the various societies of engineers, the American Institute of mining engineers, and our own iron and steel institute.

The Wisconsin Reward.

Considerable interest has been awakened in mechanical circles by the announcement that the Wisconsin Legislature had offered \$10,000 reward for a steam road wagon for agricultural purposes. In answer to many queries, G. M. Marshall, a member of Assembly, has written to the *Scientific American* as follows: "To fill the bill, the machine must travel 200 miles north and south over very poor roads that are often sunk or worn down—in the wheel and horse tracks—six inches to a foot below the common level, but with a ridge in the center, the ridges being impassable for a horse; more so for the wheel of a steamer when we take into account the bumps and stones, avoided by a double team and left in the center ridge. Our wagon track is about four feet six inches outside, and that must be the gauge of a steamer, which machine should not weigh more than two tons and must be so arranged that it will climb steep and hills, cross poor bridges, run easily over bogs, stumps and grubs, and out of ruts, etc., just as a loaded lumber wagon does; and it must travel at the average rate of five miles per hour, and, in the language of the law, 'be a cheap substitute for horses and other animals on the highway and farm.'"

The Wisconsin farmers evidently desire to get the worth of their money. It is a wonder they did not add that in case of flood the wagon should be able to climb a tree to keep out of the wet. By the terms of the law, competition for the reward is only open to Wisconsin-citizens.

A Cold Twisted Rail.

In the blacksmith shop of the Cambria iron works, several employees, under the direction of Mr. D. N. Jones, mechanical engineer of that incorporation, have just concluded twisting one of the steel rails manufactured at the industry, by way of experimenting upon it. One end was fastened permanently, and at the other a casting similar to an ordinary capstan head was fitted on. By means of levers the twisting was done gradually, the rail being cold, and the operatives gave it nearly nine turns before getting through. The rail was so uniform in quality as to leave it almost impossible for the eye to detect the least irregularity in the entire length, and there was not the sign of a flaw in any portion of it. As an indication of the excellence of manufacture of the steel rails turned out by the Cambria works this test is a most satisfactory one, and a great many persons have been led by curiosity to see the one which was experimented upon.—*Johnstown (Pa.) Tribune*.

Irrigation in India.

The Academy of Sciences held a meeting on Monday evening. President Davidson delivered the first of his lectures on the subject of irrigation. During his recent travels abroad Prof. Davidson has made a study of the systems of irrigation in the different countries visited and will address the Academy on each of them. The paper on Monday was devoted to Indian irrigation and was extremely rich in interesting details, and in the value of its conclusions applied to the necessities of artificial water-courses in California. The lecturer said that the Indian canals had not paid private capital, and had been assumed by the government, which is projecting and building a magnificent system of irrigating works. The people of India are deficient in self reliance, but have a plodding industry, and look to the government for aid in seasons of drouth. Their implements are so contrived as to secure minimum results from a maximum of labor. The government engineer makes his agreement in the native language or dialect with native contractors, who furnish the laborers and control them, and though these generally contrive to do as little work as possible with the least effort, contracts are filled in time and specifications. The lecturer described the Gangetic plains and other valleys of India, which present many features similar to the country adjacent to the Rocky mountains and Sierra Nevada range. The Himalaya Mountains are the great storehouse for the gigantic arterial water system, and the mountains of the Pacific slope are to furnish inexhaustible supplies for our valleys. The completion of the government engineering projects will add to the commercial prosperity of British India and add to the stability of the government. The English engineers found themselves obliged to discard the precepts of science in some particulars. Professor

Davidson stated that he inspected all the works in the country, under governmental auspices, and had every facility to note the labor and scientific problems. Though as lazy that an Englishman's patience would be exhausted and an American go wild, the skilled laborers execute masonry and other work equal to our own. They have no machinery. The common laborer receives six cents a day, the skilled mechanic twelve cents.

The Professor gave it as his conclusion on the subject, that the hydraulic architecture to be built in California, could be constructed at less cost in the aggregate than those in India. We have steam and machinery. Forty thousand men were at one time employed by the Indian government on the canals. In answer to a question from a member, Professor Davidson stated emphatically that his calculations were on the basis of white labor at fair wages, and not Chinese cheap competition, a question and answer which proved the exciting cause of a little scientific smiling. The paper, which was very elaborate, was illustrated with maps, and was listened to with the closest attention. A vote of thanks was passed.

THE HEBREW AND CAPITAL PROMISEMENT.—Our readers are very generally aware of the great effort that has been made to save the life of the Hebrew Rubenstein, who has been sentenced to be hung, at New York, on the 24th inst. It is claimed that he is a victim of circumstances, and that his innocence can be made to appear if he can only get a new trial. His co-religionists evidently believe him innocent, and that belief is, no doubt, greatly strengthened from the fact that he is the first of his faith upon whom the death penalty has ever been pronounced in this country. The Jews are naturally proud of this record; and thus, although the accused is poor and belongs in the lowest stratum of society, no effort or money has been spared to procure a new trial. These efforts were crowned with success just in the nick of time, and the coveted stay of proceedings obtained.

MINING SUMMARY.

THE following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

BUTTE.
MORRIS RAVINE AND CHEBROKE.—Groville Mercury, April 7: At Morris ravine, in the Hendricks claim, four chiefs were at work sending a large stream of water from each upon the bank of soft earth, which seemed to melt away before it. In this claim the bank upon the right hand is continually breaking away and sliding down into the ravine. A portion of the earth seems to be a kind of paste, and as fast as the earth in the ravine is washed away, this slides in and fills up the space. Owing to this, the workmen do not seem to make much headway, and are continually at work upon the top dirt that pays but little. Sometimes the moving mass will become stationary for a time, and quite a piece of bedrock is cleaned up, always with the best of results. This ravine is still one of the richest places on the earth. Where the mining is now being carried on the gold is coarse, and there is a good deal of it. It will be some years before all of this part of the ravine is mined out. As capital is now turning this way for new fields in which to invest, it will not be long before water will be brought here in quantities sufficient for all the purposes needed, and then we shall be able to tell a tale of mining never before equaled in this State. At Chebroke we met George W. Dyer, foreman of the Spring Valley company's crew of men. It was not long before we received an invitation to visit the claim and see the place where \$95,000 worth of gold dust had been taken out within the last 30 days, and where as much more will come from the same place. A road and an island in the claim—it seemed like an island, as the earth had been washed away on all sides down to the bedrock—standing up in the form of a cone, about 30 feet high, with a diameter at the base of about 450 feet or more, were planted six chiefs. When all were in operation at the same time, the noise was not unlike that of a mighty cataract. One of the chiefs has a seven inch nozzle, and sends a stream of water that would soon level to the ground the most substantial brick building in the county. It tears up the earth in great flakes, sending mud, stones, water and gravel high in air, while a stream of muddy water is running into the flume, carrying with it the gold, which alone is the cause of this terrific onslaught. The company has an abundance of rock ground before them. An immense derrick has recently been erected, supplied with a sturdy gurdy wheel, run by water, which is contrived as to be worked by a few men. It catches up rocks weighing tons and swings them out of the way with ease and rapidly. About 200 men are employed about the claim.

CALAVERAS.
MINING ITEMS.—Calaveras Chronicle, April 8: There is no cessation of work in the numerous hydraulics in this vicinity. Cook, Haywood & Cook are running their great hydraulic on the Calaveras day and night. They are using 500 inches of water under a 250-foot pressure. The Earl & Raynor, owners of the most powerful hydraulic, have just finished cleaning up after a somewhat extended run. The ground is so rich that they are compelled to empty their flume frequently. Veith has also taken up his rifles lately, and is now ready to resume panning. Mozer, of Spring Valley claim, is also cleaning up, and is taking out a sum that would be a fortune to many ambitious men. Cook & Co., at Red Hill, have got through with the deep part of the claim and are washing surface. We are glad to know that the ground is yielding well. The chances are good that there will be no diminution of the water supply until late in the season, and that hydraulic operations can be continued until a much later date than usual. Rich ore has been struck in the Josephine mine at West End. A contract for sinking the shaft has just been let. Gamble, Ellsworth & Co. have just concluded a crushing of 100 tons of ore in Clark's mill at Railroad. The rock was divided into two grades, the first paying about \$40 and the second \$15 per ton. Lewis & Fairchild have lately discovered a new lead in the Glencoe district, and are taking out a crushing of good ore. The progress is being made in putting up the San Bruno machinery. All the water was got out of the Crassopher last Thursday. Additional stamps have been put in motion at the Gwin mine—46 in all. An abundance of good ore is being taken from the 1100-ft stopes to keep the batteries in constant operation, and the yield of the mine is from \$12,000 to \$15,000 per month. The outlook for the mine is very encouraging, the prospect being good, that the mine now being worked will net more money than did either of those near the surface.

COLUSA.
AMOR MINE.—The following is from the monthly report for March of the Superintendent: Amount of ore reduced, 1,608 tons—23 days' run with new furnace, and six days with the old. Production, in flasks, 84; pounds, 6,426; percentage, 1.99. We are now in good working order, with both furnaces. Have commenced to make adobes. This will give us a chance to sort our rock, and we can commence to accumulate ore for next winter. Our expenses have been large this month, on account of permanent improvements. I have just opened new ground in north end of mine. The lower gulch tunnel is in 442 feet. We have made 100 feet this month; 51 feet more brings us in connection with the shaft—which will be completed by first week in May. This work will give a large percentage to the resource of the mine. The bank of the gulch is looking well, and the indications are that we have enough ore in this part of the mine to keep the furnace running all summer. If the price of quicksilver should advance, we have a fine prospect before us. The indications are that we have several years' work before us in the lower gulch tunnel. This month I have been giving particular attention to the high part of the mine, 300 feet above the east end works, where I am satisfied we have a large body of ore yet unseen. The mine in general is in good condition, and will continue to pay, unless quicksilver should go below 30 cents per pound.

FRESNO.
QUARTZ MINING.—Expositor, April 5: It is strange that with the best of the quartz veins known to exist in Fresno county not a single mine has been developed sufficiently to be pronounced a permanent paying mine. Many of the veins prospect exceedingly rich, and the surroundings are such as to indicate that they are permanent mines, but from some cause or another they are not fully and thoroughly prospected. The major portion of the quartz ledges have not been prospected to a greater depth than three or four feet. The work now being prosecuted on the Confidence mine is more important than anything yet attempted in the county. If a good ledge is developed by the tunnel at the depth of 150 feet, it will probably stimulate other companies to prospect their ledges to a greater depth.

INYO.
TUNNEL.—A correspondent of the Californian writes that the claimants of this mine had worked the lead for several months and so satisfied some San Francisco men of its great value as to induce them, for a one-half interest, to put up a mill. Mr. Harley, the purchaser, had already shipped the machinery, and ten tons of it is now on the way from California.

FURNACE FOR THE KEARSARGE.—Inyo Independent, April 7: Mr. L. C. Gray, of the Kearsarge mine, will soon be here with a furnace with which to roast the richer but more rebellious ores from the Kearsarge.

It is a "Buckner" furnace, and was shipped from Cincinnati, its place of manufacture, on the 17th of last month.

KERN.
ANTIMONY MINE AT SAN EMIDIO.—Bakersfield Southern Californian, April 6: The furnace is now being erected. The chimney is 75 feet in height. From eight to 10 tons will be smelted at the furnace, and the second furnace will be constructed during the month. The work of the furnace is under the direct superintendence of Mr. Madison, from Newcastle, England, whose life has been spent in working similar ore. Messrs. Star & Madison, of San Francisco, have prepared 33 furnaces for refining the ore from this mine, and are now awaiting the first shipment. They will refine from 75 to 100 tons per month of crude ore. The rock is valued at from \$40 to \$50, the crude ore from \$80 to \$100, and the Star regulus \$300 per ton. In New York, about 10 tons of the rock have been sent to different parts of the United States and Europe to be tested. The rock sent to Messrs. Chandler & Co., of New York, yielded 63 per cent of antimony. The rock is composed of antimony, silver, nickel and sulphur. The crude ore consists of 75 per cent of antimony and 25 per cent of sulphur.

LOS ANGELES.

PINO MINES.—Los Angeles Express, April 8: Mr. Jones, of the firm of Jones & Noyes, has exhibited to us a piece of gold, about two pounds, which was ground eluted out of a mine belonging to himself and others in six days by three men. The gold is very pure, and is worth about \$19 per ounce, and the package shown us would therefore be worth about \$460. The company have a very large claim, which is located in the Flin placers, about 50 miles from here, at the edge of Ventura county, where it joins Los Angeles. Mines in that vicinity have been worked on and on for the past 40 years, and a great deal of gold has been extracted from them. The entire region is auriferous, and good placers may be found almost anywhere. The great difficulty to successful mining has been in the paucity of water. A number of schemes have been inaugurated at intervals to bring water to these placers from Elizabeth lake, and two years ago very extensive work was done on a large ditch from that point.

NAPA.

ETNA.—St. Helena Star, April 8: The stockholders of the Etna mining company held a meeting at Napa, last Monday, and elected seven new trustees to serve for the ensuing year. The company includes a number of stockholders in St. Helena. It is contemplated to raise what funds may be needed in small assessments, so as not to bear too heavily upon stockholders, and by easy stages place the mine in a position for business. It is proposed also to sell the engine and pumps belonging to the company, which under a true line of policy are not expected to be needed. The Silver Bay will probably be the future seat of mining operations.

NEVADA.

GRANITEVILLE.—Transcript, April 5: The Eureka Lake company, the North Bloomfield and Milton mining company, have a large force at work on their ditches to clear the snow out, and expect to have them all running by the last of this week. If another heavy fall of snow does not catch them out. The California mill is running to its fullest capacity. The company are taking out a considerable quantity of rock from the Rocky Glen mine, will commence crushing in a few days. Hebert & Co., who have a fine ledge, and have taken out a considerable quantity of rock from the Rocky Glen mine, will commence crushing in a few days. Hebert & Co., who have a fine ledge, and have taken out a considerable quantity of rock from the Rocky Glen mine, will commence crushing in a few days. Hebert & Co., who have a fine ledge, and have taken out a considerable quantity of rock from the Rocky Glen mine, will commence crushing in a few days.

SAN BERNARDINO.

PAYTON.—San Bernardino Argus, April 6: The last six tons of ore taken out by the McFarland assayed \$2,350 to the ton. They take out about \$50,000 a month, and it costs them \$300 a month to run the mines.

SISKIYOU.

EMPIRE.—Yreka Journal, April 7: The Empire quartz ledge, on Empire creek, below Humboldt, on the opposite side of Klamath, still continues to prospect rich, and the company intend opening it on a more extensive scale, by running a tunnel to strike it lower down, in order to afford drainage and more successful working of the mine. The company have also let a contract to sink the shaft 50 feet further down the top, and will run their shaft in crushing the quartz on hand and to be taken out, until they can make arrangements to put up a mill.

CHINESE MINING.—The Chinese hydraulic company, who carry on hydraulic mining on Spring gulch, north of town, and have a lease of the big ditch, sent out a large gang of Chinese yesterday to repair the flume, and cut out the ditch towards its head, so as to keep up a supply of water from Shasta river when the feeders in this vicinity give out during the summer months.

Nevada.

WASHOE DISTRICT.

YELLOW JACKET.—Gold Hill News, April 6: The prospecting operations in this mine are now principally confined to the developments of the ore vein at the point where the body of rich ore was struck some two weeks since. At that point drifts have been accumulated since the last of this week, if another heavy fall of snow does not catch them out. The north-east drift from the bottom of the winze on the 1940-ft level is also looking very favorable for striking the same body of ore. The same may also be said of the southeast drift from the bottom of the south winze on the same level, as almost precisely the same formation and in fact both north and south winzes are met with in the middle cross-cut before striking the ore.

MEXICAN.—The only work now being done in the mine is the running of the northeast drift on the 1455-ft level. The course of this drift has been changed until it is now running east of and parallel with the ledge. In places where the drift has touched the quartz it shows finely.

CONFIDENCE.—The face of the main adit tunnel, following the vein northward, is still in good milling order, but owing to bad air, full dumps and an upraise which is being made at that point in the heat of the ore body, work in the face of the drift is temporarily discontinued. Nothing being done in or

suspended for timbering purposes, has been resumed and is being pushed actively ahead, the bottom in good blasting ground.

UNION CONS.—The north drift on the 1300-ft level is being steadily pushed ahead, the face in more favorable ground than for some time past. The bottom of the winze below the 1300-ft level is in quartz and low grade ore, and is looking well.

CHARLES POTTS.—The extraction and milling of ore was resumed on the 1st inst. There are no changes to note of either of the prospecting drifts on the 1250 and 1350-ft levels. Sinking the new combination shaft is making splendid progress.

CALIFORNIA.—The breasting of ore and its extraction was commenced on the 1500-ft level on the first of the month, and yesterday morning the California mill, with a daily crushing capacity of 300 tons of ore, commenced reduction. No mine on the Comstock ever so systematically opened and prepared for a favorable beginning, and no mine on the Comstock ever had at one time such an immense amount of rich ore ready to hoist to the surface as the California. While the number of tons taken out this month must be limited, on account of the inability of existing mills with which to crush it, the character of the ore now being extracted is such as to leave no doubt of the payment of a handsome dividend at the end of the first month's crushing. The ore will probably yield from \$500 to \$700 per ton. Sinking the winze below cross-cut No. 6, on the 1550-ft level, to connect with the Ophir mine, is going steadily progress, the bottom still in rich ore. The north drift on the 1400-ft level has not yet connected with the Ophir, a survey made showing the distance to be run to be greater than supposed.

WARD.—This mine comprises the old Ward location, lying immediately south of and adjoining the Julia, along with 400 feet of ground segregated from the Julia. A stock dividend of three-quarters of one share to each share of the mine was given to the stockholders of the Julia company in consideration of the purchase of the company's ground. To obtain a working capital a limited number of shares were readily disposed of to men of capital at \$3 per share, leaving a reserve of 27,500 in the hands of the company. Yesterday morning ground was broken for a fine three-compartment shaft at a point 1,450 feet south and east of the Julia shaft.

CONSOLIDATED VIRGINIA.—Daily yield, 650 tons of ore. This decrease in the amount of ore extracted is due to no change in the mine whatever, but is caused by the strutting up of the California mill, with a crushing capacity of 300 tons per day, on ore from the California mine. This mill makes a difference in the amount of ore extracted of 900 tons, and a corresponding reduction in the monthly bullion receipts. The mine shows no visible change during the week, and the bullion returns for March amounted to the neat little sum of \$3,624,218.72. The usual dividend of \$1,050,000 was declared yesterday, with a large reserve carried over for time to come. Sinking the O. & O. shaft is going steadily ahead, although the flow of water at the bottom interferes to some extent with the progress of the shaft. The east drift on the 150-ft level, running down the O. & O. shaft, is steadily advancing. The diamond drills being used well, and are expected to prevent at any time the flooding of the drift by water.

OPHIR.—Daily yield, 150 tons of ore keeping the mills all running up to their full crushing capacities. The ore hoists on the 1600 and 1200-ft levels show no changes worth noticing during the week. The east drift on the 1600-ft level has penetrated to the ore vein, which is showing finely at that point. The upraise above the 1200-ft level is connected with the east drift on the 1100-ft level is making steady progress to very favorable ground. The east drift on the 1100-ft level is still in quartz and low grade ore. The east shaft has been cleaned out and repaired to the bottom on the 1700-ft level. The new incline machinery was started up for a trial a few days ago, everything working with the utmost perfection. The new office is nearly completed. With the present favorable opening the yield of bullion for this month will, without doubt, be considerably increased.

JULIA.—Sinking the shaft is making the usual good progress, the bottom still in soft clay and porphyry and quartz. The main southwest drift on the 1400-ft level is being steadily pushed ahead, the face of the winze showing change during the week. The main southwest drift on the 1400-ft level is rapidly advancing, the face showing more favorable indications.

HALE & NORCROSS.—The water stands at about the same level in the shaft as heretofore reported. The old machinery is being taken out and excavations made for the foundations for the new and powerful pumping machinery now in course of construction. **BULLION.**—The main southwest drift on the 2000-ft level of the Imperial shaft is steadily advancing, the face in the black dyke that is almost invariably found lying next to the west wall of the ledge on that portion of the Comstock. The material in the face of the drift is gradually softening, with strong indications of water. The raise from the 1700-ft level is steadily advancing, without change. The winze being sunk below the 1400-ft level to connect with this raise is also making good headway. Sinking the main incline below the 1400-ft level is also making steady and favorable progress.

CROWN POINT.—The cross-cuts on the 1600-ft level have developed a fine ledge of quartz and ore 65 feet in width, but nothing whatever that will pay for extraction and milling. On the 1700-ft level the ledge is much wider, and well defined, but, like the level above, shows nothing better than low grade ore. Work is being energetically carried ahead at all points.

LADY BRYAN.—The entire mine is shut down in order to take out all the old hoisting and pumping machinery and put in new, of the same pattern and power as that now in use at the Caledonia and Dayton mines. The mine was never showing better than at the present time.

SIEBERA NEVADA.—Sinking the main shaft is going steadily forward without change or hindrance. The east and west prospecting drifts on the 1500-ft level are being steadily advanced, with no important changes to report. The prospecting drifts on the 1250-ft level are also making good progress, and are looking quite favorable for the speedy development of a much more encouraging mine. The south drift on the 1000-ft level, running to connect with the bottom of the winze from the 700-ft level of the old shaft, for air purposes, is making good headway.

SILVER CITY.—The mill is kept running to its full capacity on ore from the mine, and a good showing of amalgam is being made, giving assurance of an excellent clean-up. The first shipment of bullion will be made the first of May. The ore breasts and scopes from all three raises, above the main tunnel, on the 1000-ft level, are showing and yielding splendidly, and the face of the south end drift is in low grade ore.

JUSTICE.—The extraction of ore has been commenced from both the 400 and 600-ft levels, and it is being sent to the mills for reduction. The main south drift on the 500-ft level is being cleaned out and repaired as rapidly as possible. The main north drift on the 500-ft level is being pushed steadily ahead, opening the 1000-ft level is going steadily forward with good prospects of soon reaching the ore vein.

DAYTON.—The north and south drifts, on the 500-ft level, are steadily advancing without change of inclination. No change to report of the main south drift, on the 300-ft level.

BELORE.—Daily yield, 650 tons of ore, keeping the mills steadily running. The ore breasts show little or no change during the week. The mine is looking well throughout. The ore prospects in the winzes below the 1600-ft level are steadily on the increase. The erection of the new pumping machinery is making satisfactory and fast progress.

SILVER HILL.—The water was drained from the main incline during the latter part of last week, and the sinking resumed. Two or three heavy blasts were exploded, when a fresh flow of water was encountered, which drove the men out and has prevented any work in the bottom since that time. The heavy 14-inch pump

columns are being now placed in the incline, and it will be but a very few days before the water is extracted and the sinking resumed.

BALTIMORE AND AMERICAN FLAT.—Sinking the main incline is making excellent progress, the bottom in good sinking ground. The main east drift on the 1050-ft level is steadily advancing, without change of interest. The north and south drifts, on the 1050-ft level, both show an increase of quartz, which is also generally increasing in value as the drifts advance.

UTAH.—Sinking the shaft is going steadily ahead, the bottom in hard blasting rock. The flow of water is still very strong and impedes the progress to a slight extent. A sufficient depth will be reached in two weeks, more to permit of opening another station at the 750-ft level, which will give a depth of 350 feet of entirely new ground to prospect.

GOULD & CURRY.—The repairs to the shaft are being pushed steadily ahead. The north drift on the 1700-ft level is being repaired and put in working order as fast as the work can be accomplished.

SULLIVAN.—The main cross-cut east is now in 265 feet from the west wall, and is being driven ahead lively, both day and night. No sign of east wall as yet, and better ore and more of it at present in the drift than ever before. A strong flow of water is coming in, yet not enough to impede work.

GLOBE CONSOLIDATED.—Both the north and south drifts on the 350-ft level are steadily advancing along the line of the ore vein, the face of each in very favorable ground. It is the intention to commence the cross-cutting of the ledge, both north and south, in a very short time.

NORTH CARSON.—The new hoisting machinery for the mine has arrived and is being put in position as fast as possible. The mine itself is showing splendidly, with increasing good prospects as further development is made. The shaft is being steadily advanced, with the best of Belcher. There is nothing doing in the mine at present, except the cleaning out and repairing of the connecting drift with the Gould & Curry, on the 1700-ft level.

KOSKUTZ.—The main south drift on the 350-ft level is showing some rich gold ore. The prospects of the ledge going south is steadily on the increase. The main drift on the 500-ft level are steadily advancing, running parallel with the ledge and occasionally cutting thin chutes and streaks of fine quartz and ore.

LEVATHAN.—Shaft 597 feet deep. Bottom in ledge matter, principally low grade ore, with rich streaks, which give high assays.

IMPERIAL.—The north drift on the 2000-ft level is steadily advancing, the face still in ore of a fine character. There are no changes to note in other portions of the mine except that using the air on the 2000-ft level has suspended all work on the 1300-ft level for the present.

NORTH CONS. VIRGINIA.—Sinking the shaft is making excellent progress, the bottom still in soft porphyry with streaks of quartz of a very favorable character.

SAVAGE.—The excavations for the new pumping machinery are going steadily forward. The stations in the shaft for the new pump-holes and water tanks are nearly completed.

AMAZON AND GLASGOW.—The water has been drained, and sinking and prospecting the 300-ft level resumed, with every prospect of speedy and valuable ore developments.

NORTH DAYTON.—The face of the main north drift shows continued improvement, the rock getting softer and more stringers of quartz coming in, which give good assays.

TRONAN.—The hoisting works building and the carpenter shops are fast approaching completion, the work being driven ahead with all possible energy.

SENATOR.—Work has been resumed, and the shaft is being drained of water. As soon as the water is drained sinking will be resumed. There is no flow of water at this time.

WEST BELCHER.—The drift west for the ledge is now in 52 feet and driving ahead at a lively rate, the machinery and everything working well.

CALEDONIA.—Sinking the shaft is making good headway, notwithstanding the steady, strong flow of water. It is now down 1,015 feet.

PROSPECT.—Diamond drill still in the ore vein and giving very fine assays from the horings. Shaft progressing downward at a good rate.

NIAGARA.—The main incline is now down 265 feet, the bottom in a very favorable formation, and the sinking making good progress.

VIVIAN.—During the week 22 feet have been added to the main south drift. The main north drift on the 300-ft level has again passed into fine ore. The ore is now being mined.

SUTRO TUNNEL.—Total length this morning, 12,740 feet. Material in face of header softer, with more water coming in.

(Continued on Page 252)

SINGULAR COINCIDENCES.—On Tuesday, the 23d of February, at the same hour of the day and the same minute of the hour, Deacon Noah Pesse and his wife Lucinda, of Ellington, who were united in marriage over 63 years ago, passed away from this life together, and entered upon the life to come almost without any separation, even by death itself, and this not by the same disease, but by diseases entirely distinct and unconnected. Both were over fourscore years of age. This may be well called a rare occurrence. —Rockville (Conn.) Journal.

We can match the above by the following occurrence which is said to have recently reached its climax at the places named in this State: "A few years ago, there resided at the Mission San Jose, in Alameda county, two young ladies, between whom, although not of kin, a strong friendship existed. They were married at the same time and by the same service. They took up their residences, one at Hayward and the other at Alvarado. In the course of time they gave birth to children on the same day, the birth of one child preceding that of the other by two hours. Three weeks later both children died on the same day, the eldest dying just two hours before the other. Three weeks after the death of the children both mothers died on the same day."

BISMUTH ORES.—J. Mosheimer writes as follows to the Sonora (Tuloume county) Independent: "Amongst the great variety of sulphurets, and other ores which abound in your county, I have no doubt that by careful searching, bismuth can be found—as I had once a sample, but did not hear of the locality. Bismuth is found as native metal, then in sulphurets combined with copper, iron, arsenic, tellurium, selenium, etc. There is also an oxide of bismuth of a yellowish color, looking like ochre (oxide of iron). It is now a valuable metal; is worth about \$3 a pound. It may be found in many ores in your county, but I doubt very much if ever a piece of ore from there has been tried for it. My attention has but lately been called to it, and it may be of much value to some of your prospectors as it would be to find a gold mine."

THE ENGINEER.

Great Bridge Enterprise.

This appears to be an age of stupendous enterprises in the way of bridge building. No sooner is one work of this kind completed than we have multiplied projects for others, each more difficult and daring than its predecessor.

The bridge now in process of construction between New York and Brooklyn is the most formidable work of the kind yet undertaken. Since the inception of this enterprise numerous others have been started or suggested in various parts of the country. It is now in contemplation to build a second bridge to connect New York with its suburban population on the western shore of Long Island, a few miles above that which will soon span the East river from the City Hall park.

There is also another for which a contract has just been let, which is to cross the Hudson at Poughkeepsie by five spans of 520 feet each. This will be what is termed an undergrade or deck bridge, having railway tracks above and a carriage way below. Its total length will be 4,500 feet. The erection of the structure is understood to be a preliminary step to the proposed opening of a new line of railroad between New York and Chicago, which, it is affirmed, will be but 921 miles in length, or 59 miles shorter than the shortest existing route.

A gigantic new bridge is also about to be built across the St. Lawrence at Montreal, to accommodate street cars, carriages and foot passengers, as well as railroad traffic. A viaduct 4,800 feet long, in 20 spans, will conduct from Sherbrooke street to the river, five spans of 600 feet each will cross the river to St. Helen's island, which will be traversed by a viaduct with 20 spans of 120 feet each, while 12 spans will cross the unnavigable channel south of the island—making the total length of the bridge 10,200 feet, or nearly two miles. The bridge will cross the navigable river channel at an elevation of 130 feet above the water!

The longest iron bridge in the United States is the St. Charles bridge over the Missouri river, which, with its seven spans and opposite river approaches, is 6,535 feet in length. The greatest engineering difficulty which had to be encountered in planning this structure, was the strength required for its central piers, the caissons for constructing which had to be carried down from 54 to 76 feet through water, quicksand, large boulders and heavy imbedded driftwood, and planted with sufficient firmness to resist freshet rises of 40 feet, with a current of nine and a half miles an hour of flood speed, often carrying floating islands 300 feet in diameter and drawing 20 feet of water. All these difficulties have been overcome at nearly double the estimated cost, however, and the bridge now stands as one of the proudest monuments of successful American engineering.

A Second Channel for the Erie Canal.

One of the latest engineering projects in America is the construction of a second canal for the Erie canal. This project is designed to take the place of the proposition for widening and deepening that great interior water way. The expense of constructing a second canal will be but little more than that which will be required for widening the present one, while the relative advantages will be much greater. The proposition is to commence at its western extremity and give a uniform down grade of about seven inches to the mile, by which a three mile current will be established, and to use this second canal for transportation eastward only—utilizing the force of the current as a motive power. It is, moreover, proposed that the new channel shall be three feet deeper than the present one, so that as the excess of transportation will always be in the direction of the current, boats going eastward may be able to draw three feet more water than on their return trip. The present canal admits a draft of six feet; by increasing the depth to nine feet most of the sailing vessels now on the lakes could make the passage seawards by the canal fully laden, and return with a limited cargo—all that the business will admit of. Of course such navigation will require the use of drawbridges.

It is claimed that by the aid of the three mile current, the down-going boats would be able to double their present speed, and quadruple the capacity of the canal, while the cost of freight might be greatly reduced, without any reduction in the present rate of tolls. It is estimated that the sum of \$35,000,000 will be amply sufficient to construct the new canal from Buffalo to Rochester, within five years from the inception of the work; then by allowing the tolls to accumulate for a few years the State might commence the construction of another section, and so on until tide-water was reached—always keeping the tolls at figures that would not allow the canal to become a financial burden. The chief novelty in the idea is the double canal, which appears to present an economical, as well as novel feature; and is one which will apply to other canals or parts of canals, whenever water is plentiful and the down grade sufficient. Communication between the two canals could be established at certain intervals by connecting channels, which, of course, would usually have to be provided with locks, as the two channels would seldom be on a level with each other.

Narrow vs. Broad Gauge Railways.

There are few questions of greater importance now being considered by engineers than the simple proposition as to the proper width of railway tracks. We have now in the United States six different gauges, as follows: Six feet, five feet, four feet ten inches, four feet eight and one-half inches, three feet, two feet and six inches, besides a three feet and six inch gauge in Canada.

English engineers formerly held that seven feet was the proper gauge for ordinary traffic, while where it was desirable to attain 50 and 60 miles an hour, a still wider gauge was required and used. Their experience, however, has led, for economical reasons, to a decrease in the width and a corresponding decrease in speed, until 25 and 30 miles an hour is now considered the highest practical speed which can be economically kept up. English engineers have thus come down to the American idea in this regard. It has been found that the operating expense for any higher rate of speed is beyond the endurance of finance. Indeed, it is said that every broad gauge road has thus far proven a financial failure. It moreover appears that even with a broad track already graded and the rails in place it is found expedient to incur the expense of narrowing the track, even at the great cost thus involved in the change of rolling stock as well as of rails. The American idea is thus coming into general acceptance in England.

The question at once arises, how far may the gauge be reduced? This is as yet a matter for future solution. Just now the extreme narrow gauge is favored for all short feeding lines and a moderately wide gauge for principal and through roads. So much enquiry has lately been elicited in this direction, that about a year ago an interesting pamphlet containing the history and statistics of narrow gauge railways in this country, was published by Mr. Howard Fleming, of Philadelphia. A second edition of this work has just been issued, containing many additional features of interest, embracing a record of the progress made during the past year, statistics of mileage since 1871, reports of the various roads, with grades, curvature, weight of rail, construction formula, rolling stock equipment, financial condition, etc. The new edition has been very much enlarged and improved, and will be a valuable source of information for all who are interested in this class of roads. Mr. Fleming's address is 311½ Walnut street, Philadelphia.

The Proposed English Channel Tunnel.

A late Paris correspondent of the London Times says that the question of the Channel tunnel is steadily advancing. An international company, it is well known, was formed, with a capital of \$800,000, to be furnished in equal moieties by French and English shareholders. The first step succeeded, and the English company, which was behind in raising its capital, has been for some time provided with the requisite sum. A second step was then taken. The promoters were told that, as they meant to risk \$800,000, it was better that they should immediately appeal to capitalists, and constitute themselves definitely.

This advice was not followed. They thought it better to risk their own capital, and not appeal to the public until experiments had been made and nothing was left to chance. This determination was promptly justified. The preliminary expenses have only amounted to an insignificant sum, and the promoters have already acquired a certainty that they may make decisive experiments; and when these have been made they will resolve either on the entire abandonment of the scheme, or on a definite enterprise, guarded against all eventualities and miscalculations, so that whenever they present themselves before the public they can precisely determine the time, cost and nature of the undertaking.

AGRICULTURAL ENGINEERING.—Scientific agriculture has made such progress in England that it has been found advisable to organize there an "Agricultural engineering association" to look after and advise with regard to the general interests of that industry in England. Among other matters which this association has had under advisement during the past year is a memorandum to the Royal agricultural society of England, in which they complain, among other things, of the multiplication of agricultural shows, and increased charges on entry and freight. The most weighty, however, of the complaints is the want of time of the judges to estimate the value of an agricultural implement, and they submit "that no judgment should be pronounced on any standard agricultural machine unless it has been at work, performing its ordinary duty, for a considerable time under the eye of the judge. This would be most satisfactorily accomplished by placing the implements in the hands of experienced agriculturists for at least a whole season, on the conclusion of which they might be submitted to dynamometric trial. After such probation it would be sufficient if an accurate and detailed report were given of the duty performed and condition when ceasing work. Steps should also be taken to compare implements so tried as to their construction with the ordinary commercial productions of the same exhibitors."

USEFUL INFORMATION.

Hints for Practice.

Glue holds more firmly when applied to the fibers cut across than to a cut parallel to the fibers.

Soaking wood at 80 to 100 degs. C. in linseed oil for two or three days increases resistance to fracture. It is believed that the increased toughness is due to increase of the density of the wood.

TASTEFUL ORNAMENTS may be made of natural leaves and sprays artificially frosted. This is done by means of powdered glass, which can easily be obtained by pounding some bits of glass with a heavy hammer, care being taken to protect the eyes against flying splinters. Dip the objects in thin gum water and shake the powdered glass over them. When dry, handsome bouquets can be arranged.

GLUE frequently cracks because of the dryness of the air in rooms warmed by stoves. An Austrian contemporary recommends the addition of a little chloride of calcium to glue to prevent this disagreeable property of cracking. Chloride of calcium is so deliquescent a salt that it attracts enough moisture to prevent the glue from cracking. Glue thus prepared will adhere to glass, metal, etc., and can, it is said, be used for putting on labels without danger of their dropping off.

THE *Housekeeper* gives the following suggestions for utilizing old tin cans. Take off the top of the can, punch holes on opposite sides near the rim, put in a wire bail, and you have a little bucket, which may serve for a paint pot, to keep nails in, or other handy purposes. Take off the top, cut to the proper shape, and fasten on a handle by means of a screw through a hole in the bottom, and a useful scoop may be made. A saucerpan for small masses may be made by cutting down a can, leaving a strip to be bent at right angles, and turned round a stick, to serve as a handle. A coarse grater for crackers, etc., is easily formed from a piece of tin fastened to a board. The holes in the grater should be made with an old three-cornered file.

The Uses of Tannery Refuse.

The *Journal of the Society of Arts* describes a number of uses which can be made of tannery refuse. The refuse consists of untanned dried pelt or glue pieces, fleshings, hair, lime deposit, and spent tan. The glue pieces are used for two purposes, the principal of which is the manufacture of gelatin and isinglass. For this industry thousands of tons of the scraps are sold. The dry untanned portions find their second utilization in paper making, and they are also used for the manufacture of peckers or hammers, for knocking to and fro the ever-flying shuttle. Ordinary size is made from the flesh refuse of the hide, and is extensively used by paper hangers, cotton spinners (to give firmness to the thread), and carpet manufacturers. As to the hair, there has been little demand for it since speculative builders have discovered a mode by which ceilings can be made to retain their positions for a time without its use. Unhappily the demand for cheapness has stimulated the makers of inferior clothing and blanketing to mix hair with wool, thus rendering the fabric heavy without in any way adding to its warmth-retaining capacity. Hair is also used in the fabrication of horse cloths and railway rugs, and, strange to add, the cheap (so-called) sealakin jackets largely sold in England are made from the same material.

A profitable use for spent tan, other than as fuel, remains yet to be discovered. Liebig says that it is valuable as a manure when wholly rotten; some have tried to turn it into charcoal, and to light their tanneries with its gas, but the results have not been very satisfactory. A new process for using this refuse instead of charcoal in the manufacture of tin plates has lately been tried in Wales, and seems likely to be advantageous and useful.

The lime grounds or deposit, although not used for the purpose, is an excellent manure. It contains a mixture of salt, blood, lime, and gelatin. Its analysis is as follows: Moisture, 54.05, organic matter, 6.80, silicon, 2.55, iron and alumina, 0.84, phosphate of lime, 1.85, carbonate of lime, 12.42, caustic lime, 17.44, common salt, 4.05; total, 100.

PHOTOGRAPHY AS A DETECTIVE.—Recent attempts at forgery, by the alteration of dates and amounts of written checks and drafts, have resulted in investigation as to how erased writing may be rendered visible. Various chemical processes, more or less efficacious, have been suggested, but the simplest process yet devised seems to be the photographing of the unspectated paper. This is founded on the fact that certain colorless or feebly colored substances, while very slightly affecting the eye, set powerfully upon the sensitive film in the camera. Photographers are aware that a photographic proof nearly effaced through age may, by photography, be reproduced with all its primitive detail and intensity. Generally all yellowish stains may thus be brought out; and peroxide of iron in the smallest proportion, so as to be practically imperceptible to the eye, gives proof of great clearness. Common ink, says M. Gobert, to whom is due the credit of the suggestion, is a compound of tannin and oxide of iron. Now it matters little what chemical means are used to remove ink marks; for however coarsely the chemical be applied, some

traces of peroxide of iron are sure to be left either on the surface or in the substance of the paper. It is only necessary, therefore, to photograph the sheet, and to enlarge it besides to bring out in the proof the effaced writing in an entirely legible condition.

Keep Coal Under Cover.

That most of the true bituminous coals (English and American) are subject to spontaneous combustion when in bulk, and under favorable circumstances, is well known, and even when lying in large heaps, exposed to the atmosphere, there is certain waste and deterioration that takes place, attributed to a slow combustion. The waste of fuel, however, exposed to air, depends on its igniting temperature. Experiments by Greenmann, at Tarnowitz, in Germany, have proved conclusively that an exposure of bituminous coal in heaps to the action of the weather for a period varying from two weeks to a year results in a large percentage of loss. This loss is in the nature of a slow or incomplete combustion; it is greater and more rapid in large heaps than in small, and is also favored by the greater or less state of subdivision of the coal, large fragments losing proportionally less than smaller ones. The loss varies from five to 25 per cent. Varrentrapp also gives the following test: "A quantity of pulverized coal (bituminous) was placed in a tight vessel, through which a current of air could be drawn. The vessel and air were brought to a temperature of 280 deg Fahr., and the air, after passing through the apparatus, was caused to bubble through certain chemical preparations which had the property of retaining and rendering visible carbonic acid. Under these circumstances the carbon of the coal was ultimately removed by the chemical solution of the air as carbonic acid, showing conclusively that a true combustion had taken place. This combustion is so complete that in three months nothing but ashes remain."

PRESERVING SCRAMBLED SURFACE.—The composition invented by Mr. G. F. Heyl, of Charlottenburg, consists of palm oil or oil of Senegal about 20 parts; coloring matter (hydrated protoxide of iron or chromate of lead and Prussian blue), 100 parts; varnish, 20; lac, in scales or flakes, 10; pyroligneous spirit of alcohol, 120; resinous gum or euphorbia, 50; chloride of mercury, 15; and arsenic 15=350 parts.

GOOD HEALTH.

The Increasing Use of Opium.

The custom house returns show that the quantity of opium annually imported into the United States is ten times greater than it was 30 years ago.

The quantity consumed for medicinal purposes has kept steady and regular pace with the growth of population, while the increase in the use of opium as a stimulant has been, and is, greatly in excess.

A well known physician reports that he had talked with several of the most intelligent apothecaries, who told him that "the use of opium had greatly increased, especially among women." The reason given was, that doctors were prescribing it more generally to their patients, and thus the habit was acquired.

In the *Edinburgh Medical Journal*, Dr. Minnet, lecturer on *materia medica* at Surgeon's hall, Edinburgh, sounds a note of warning, impelled thereto by three cases of opium eating, all starting from physicians' prescriptions, which came before him within a few weeks.

It becomes a very serious question, in the face of such facts, how best to guard against the indiscreet prescribing of opiates.

It would be well if opium were confined exclusively to the forms in which it is generally known; but, unfortunately it is not, and here lies the great danger. Under the treacherous guise of soothing syrups, elixirs, pain killers, nervous antidotes, and a long list of nostrums, it creates an appetite that by frequent indulgence almost inevitably ends in a confirmed habit. Still worse, it is prescribed by charlatans as a remedy for the cure of persons who are addicted to opium eating. There is no means of ascertaining the quantity of such nostrums disposed of yearly, and the extent to which opium is employed in their manufacture can only be conjectured. The fact that there are so-called remedies for the correction or cure of the habit affords a significant proof of the extent to which it prevails. One "remedy" for the eradication of this disease consisted of a clear solution of sulphate of morphia, colored and sweetened. No definite directions as to quantity were given, but a dose, containing about two grains of sulphate of morphia, was to be taken three times a day by the patient, "when suffering from depression and other symptoms."

The editor of the *Medical and Surgical Reporter*, in a recent article on this subject, remarks that there is probably no true hypnotic which is innocent. But, he adds, whatever is tried, opium and chloral should be religiously reserved for those cases of positive disease where sleep is indicated.

FOOD IN FEVER.—It has been found to be a successful method to freeze beef tae, and to administer it in limps to children or patients to snook: they will take it in this form rather than any other kind of food.

Poisoned Stockings.

The *Utica Observer* of March 4th gives the following particulars in regard to a little four year old boy of that city who suddenly became seriously ill. His physician, on observing his stockings, said at once that his sickness was probably due to his stockings, which were died brown, as the doctor thought by the use of picric acid. We quote the balance of the story as follows: Last Sunday the little fellow put on a pair of brown woolen stockings. Yesterday morning he was taken very ill. He commenced retching and vomiting, and a yellowish line commenced spreading all over his body. When Dr. Tefft was called the little fellow was suffering great pain. Dr. Tefft confesses that after an examination he was unable to see why the boy should be sick until his eyes fell on the boy's brown stockings, when the thought flashed over him that the newspapers were probably right, and that there was poison in them. He had them removed at once, and found that the boy's legs were fairly yellow. He then had the mother taste the stockings, and she declared they were very bitter. The mystery of the poor little fellow's illness was explained.

Dr. Tefft, on reading upon the subject of picric acid, found that it would produce the same symptoms as those exhibited by the boy. This morning the stockings were subjected to a thorough test. A piece was cut from one of them and placed in hot water for a moment. Then placing it between the teeth a very bitter taste was perceptible, so bitter that it irritated the end of the tongue. The pair of stockings was then placed in the water. On wringing them the water immediately became discolored, assuming a yellowish tinge which could not be mistaken. There is no doubt that the picric acid in the matter used to color the stockings produced the boy's sickness. At one time the little fellow was very near death, but he is now recovering. His yesterday's attack was his first serious illness, but it is noted that during the time he has worn the stockings he has been afflicted with diarrhea, headache and stomach ache.

The stockings were not a cheap pair. They were as nicely made and of as nice a shade as any. But their effects are dangerous. This picric acid is not used alone for purely brown stockings. It is also used to dye striped hose in which that color appears. But all brown stockings are not poisoned. Some of them are manufactured by honest dealers who disdain to make use of picric acid on account of its cheapness, because they know its deadly effects. There is one sure test to apply to detect its presence. Stockings dyed with it, placed between the teeth and against the tongue, impart a bitter taste which cannot be mistaken. Ladies or others about to purchase brown stockings would do well to apply this test before buying.

Keep the Feet Warm.

Never go to bed with cold feet. Never try to sleep without being perfectly certain that you will be able to keep them warm. To lie one night with cold feet gives such a strain to the system as will be felt seriously, perhaps ending in a fit of sickness.

Cold feet shows an unbalanced circulation. The very best thing to do is to warm them by exercise; if that be practicable. If not, try dipping them in hot and cold water, alternately, two or three times, and then using vigorous friction. If that does not warm them and keep them warm, heat them before the fire, drying them thoroughly, and then correct your habits, or improve your health, for be sure that one or the other is wrong, or perhaps both.

With all the rest, if you sleep on a hard bed, with cotton sheets, in a cold room, put on an extra covering over the feet. It is very convenient to have a "feet comforter," just wide enough to cover the top of the bed and about a yard deep. This may be made of some light material (perhaps the remains of some pretty dress), filled with cotton, like a "comforter," and tacked with some harmonious color. During the day this may be thrown over the foot-board, and spread over the bed at night. The advantage of this is to secure light covering for the feet without overburdening the remainder of the body.

If you use a hot brick or hot iron, put it in the bed a little beforehand, and then when retiring remove it. To sleep with the feet in contact with it has a tendency to make the feet tender.

But better than both of these, and to be used with or without them, is the foot blanket. This may be a square yard of domestic flannel, or two yards folded of Swiss flannel, or anything else you like that is warm enough, only have it nice and clean. Fold this around your feet and ankles before you put them into the bed. If not very cold, this will often warm them, especially if you have used friction; and if warm, it will prevent their becoming cold by contact with the cold sheets. It keeps the warm air around them. It does not make the feet tender, and it is far more convenient than the hot brick or soapstone. Try it, and if you are troubled with cold feet you will be likely to keep it by you hereafter. Whatever you use, always lie full length. To "curl up" hinders free circulation.—*Herald of Health*.

DOMESTIC ECONOMY.

Practical Hints for Inexperienced Housekeepers.

I can truly sympathize with all the army of women, wives of men of moderate means in our country, who have ever before them the problem to solve, "How can we spread a table three times a day with food palatable, nutritious and economical?"

Having had 25 years' experience in the various duties of the wife, mother, housekeeper, provider, cook, laundress and common seamstress, I shall be glad to say a word of encouragement and help to the young experimenter in all these complicated duties.

It is all very well for men to tell us that women cannot cook. When a man attempts cooking he makes a business of it; he spends years in learning the art; and then he must have an assistant to wait upon him; must have the best materials at hand and the proper utensils in work with; and, finally, he will expect to be well paid for his services. Don't condemn women as cooks until they have had a fair trial.

There are certain general principles in cooking, as in other arts, which should be learned, and the knowledge of these will make all details easy. We will make cake the especial theme of this paper.

The best flour should be used in cake making; indeed, there is no economy in using cheap flour for any purpose. The best sugar for all plain cake is the coffee A. It is cheaper and better than the granulated for common use. For making very delicate cakes the pulverized should be used, being careful to get pure sugar; it is apt to be adulterated greatly. Eggs should be kept in a cool place; they heat much better to be cold. Do not try to make cake with butter which is unfit for table use. It is not necessary to have the very best; good roll butter, having no bad taste, should be used. Recipes can often be changed without failure, if, for any reason, all the materials called for are not at hand. To venture upon this, however, you must not upon fixed principles. If you have but two eggs and the recipe calls for three, leave out a third of your butter and a little of your flour; the cake will be good. If your butter is short, leave out an egg.

It is often inconvenient to weigh all the ingredients; therefore, in giving recipes, I shall, if possible, give measures only. Roll sugar before measuring it; fill the cup even full, being careful not to pack the sugar. Flour should be sifted first and then placed lightly in the measure. Use for a measure a cup which will contain just one-half pint of water. For a measuring spoon use an ordinary silver plated spoon. A spoonful means even full—not heaped. Three teaspoons rounded full of baking powder is the general rule for a quart of flour; this must always be mixed very thoroughly with the flour, dry. If your recipe is an old one, and says cream of tartar and soda, you can generally substitute baking powder in its place. If you prefer to use the cream of tartar and soda, the soda must be dissolved in water and the cream of tartar mixed with the flour, dry. If your recipe says "sweet milk," use water in its place; the cake will be whiter and quite as good. To compound a nice cake two persons should, if possible, be engaged in the work; but we will suppose the young cook alone.

First see to your fire; this should be started at least an hour before the oven is needed, so that the bottom of the oven may be well heated and the heat steady. The baking is of the greatest importance, and should be carefully provided for. Read your recipe and place all the ingredients upon the table, or close at hand. Place your butter where it will soften, but not melt. Have the baking pans ready; place a piece of paper in the bottom and butter this and the sides of the pan carefully. The shape of the pan is immaterial, but it should be deep and not bright new tin. An earthen dish should be used for mixing cake. Now break the eggs, separating the whites from the yolks with great care; beat the yolks a few minutes, then the whites, till a fine, stiff froth is formed. Set the dish containing the whites in a cool place, and on no account disturb it until it is needed. Now put the butter and sugar together and beat or stir with the hand till the mass is light and soft, then add the yolks, spices, or flavorings; then the water, then the whites of the eggs and flour, alternating the flour and eggs, till all is well stirred together; remove the hand and put the cake in the pans with a spoon. If, for any reason, the oven is not quite ready the cake may wait, if placed in a cool place, till the oven is all ready. After it is placed in the oven it should not be moved without great care. Don't open the door for inspection too often.

If the oven should be too hot place a few nails under the pan and put a paper over the cake; remove a cover from the top of the stove, but do not open the oven door. The drafts, of course, must be closed; they should always, during the process of baking, be partially closed. To learn when the cake is done pierce the loaf with a broom straw; if the straw comes out dry and clean it is done. If you have any doubt, however, leave it in longer.

The above are general directions for all the ordinary kinds of cake. For fruit cake some special directions are needed. The fruit must be washed and dried; raisins stoned and chopped; flour dusted over the fruit and then put into the mixture, just before it is put into the pans.—*Cor. Chicago Tribune*.

MINING SCIENTIFIC PRESS

W. B. EWER..... SENIOR EDITOR.

DEWEY & CO., Publishers.

A. T. DEWEY, GEO. H. STONG,
W. B. EWER, JNO. L. BOONE

Office, No. 224 Sansome St., S. E. Corner
of California St., San Francisco.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week. 1 month. 3 months. 1 year.
Per line..... .25 .80 \$2.00 \$5.00
One-half inch.....\$1.00 3.00 7.50 24.00
One inch.....1.50 4.00 12.00 40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTIONS payable in advance—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the Press promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription.

THE ORIGINAL ARTICLES in this paper are mostly set in solid type, giving in our columns one-third more reading than is contained in ordinary leaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, April 15, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Pacific Coast and Other Mines Compared; Arizona Ores for the Centennial; A New Revolving Furnace for Treating Ores, Etc., 241-9. Depreciation of Silver; A. T. Stewart; Gold and Silver Mining; California Manufactures, 248. Gems and Precious Stones, 249. Guard Against Frost; Book Notices; Patents and Inventions, 252.

ILLUSTRATIONS.—Manes' New Revolving Furnace for Treating Ores, Etc., Figs. 1, 2 and 3, 241.

CORRESPONDENCE.—Botanical Excursions, 242.

SCIENTIFIC PROGRESS.—Evaporation and Percolation; Rusting of Iron; Detonation; Salicylic Acid; Phosphide of Copper, 243.

MECHANICAL PROGRESS.—Dynamite; A New Anti-Incubator; A Suggestion for the Centennial; The Wisconsin Reward; A Cold Twisted Rail, 243.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 244-5.

MINING SUMMARY from various counties in California, Nevada, Utah, Oregon, Arizona and Idaho, 245-246-252.

THE ENGINEER.—Great Bridge Enterprise; A Second Channel for the Erie Canal; Narrow vs. Broad Gauge Railways; The Improved English Channel Tunnel; Agricultural Engineering, 246.

USEFUL INFORMATION. Hints for Practice; The Uses of Tannery Refuse; Photography as a Detective; Keep Coal Under Cover; Preserving Submerged Surfaces, 247.

GOOD HEALTH.—The Increasing Use of Optum; Food in Fever; Poisoned Stockings; Keep the Feet Warm, 247.

DOMESTIC ECONOMY.—Practical Hints for Inexperienced Housekeepers, 247.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 252 and other pages.

MISCELLANEOUS ARTICLES.—The New Fish Law; Selby Hill Gravel Mining Company; Mills and Mines about Mineral Park, 242. Singular Coincidences; Bismuth Ores, 248. Nevada County Copper Mines, 250. Improved and Successful Method of Sinking Shafts, 254.

NEW ADVERTISEMENTS.

Hercules Powder, California Powder Works, S. F.; California Watch Co.—Sale; Elamath Q. M. Co.—Sale; California Acclimatizing Co.—Assessment; "Uniform Speed," Hutton Gov. Co., Waltham, Mass.

A NEW PACIFIC RAILROAD.—If the Black hills should prove a really productive mining region the result will undoubtedly be the construction of a new railroad from the Mississippi to the Pacific. Indeed, a charter has already been asked of Congress for such a road, under the title of the "Atlantic, Chicago, Black Hills and Pacific railroad company." The proposed route of this road west of Chicago deflects northerly through Southern Wisconsin, Northern Iowa to Yankton in Dakota, thence to the Black hills, and by very easy grades to the Yellowstone and Pacific, about midway between the present road and the proposed Northern Pacific. The eastern terminus will be Boeton, and the road will be managed in the interest of that city.

AMERICAN ENTERPRISE.—Mr. Robinson, an American of New York city, is now constructing a system of street railways for Kingston, Jamaica. With Meigs in Peru, Plomb in Mexico, and numberless others setting on foot railroads and other enterprises in Russia, Egypt and other countries, American enterprise seems to be revolutionizing the world.

THE CHEMISTS of New York and vicinity have organized as the American chemical society. Officers were to have been elected and a constitution adopted on the 20th of last month.

Depreciation of Silver.

The state of affairs now existing in this city in regard to our mixed coinage recalls the history of the introduction of the "greenback", issue. At the time when it was found necessary to use the latter means of extending the government credit, by forcing a loan upon its own citizens, there was no more doubt of its solvency and ultimate ability to meet its dues than there is now. As the question did not hinge on the good faith of those in power, as now, but on the mere financial stability of the nation, which was unquestioned even in the darkest period of the war, it would seem natural that people should have accepted the national promise to pay with a better grace, since there was no escape from the difficulty. Very possibly each person (or the great majority) individually would have been willing to take the notes of the nation freely, but from the fact that any form of money must be current with all other persons in order to have circulation, the tax was too great. We cannot now see that the greenback question was at that period any more difficult of solution than it is now, and we are forced to believe that loyal sentiment and unshaken faith in the credit of the country were then powers which obtain to a much smaller extent at present.

The silver problem is in some respects very similar to this, though the difference between paper pledges and a precious metal would seem to indicate the contrary. The manifest policy of this section of the country is to keep silver up to its proper position and not to depreciate it. While it is impossible of course to dream of seeing silver a monetary standard, as was formerly the case in some foreign countries, yet there is no just reason why it should be put from its proper place. The same difficulty of adjusting the coinage to a varying proportion of gold and silver is by no means a new one, and should create no panic. The fitness and weight of silver coins have again and again been forced to be changed, in this as in other countries, and the result can always be arrived at without any of the cumbersome and complicated devices which are now being so numerously proposed.

Here in San Francisco the rush of retail dealers to protect themselves against loss has caused a too sudden and disastrous revulsion, though the matter will work itself clear in time by the natural laws of trade. But it does seem too bad to see coin which is "legal tender" outrank better coin which is not so provided for. This is putting hard money into the same position as a forced and doubtful currency, and is an anomaly which cannot long exist. We hope that the people of this city, who are most nearly interested in the welfare of silver, will, as a matter of necessary policy, if not of simple fair dealing, unite in the effort to maintain confidence in that upon which we, of all others, are most dependent. Though the silver comes chiefly from Nevada, and altogether from outside the State, the ownership and control of the mines are centered here.

A. T. Stewart.

The overland dispatches on Monday morning brought news of the death of A. T. Stewart, of New York City. Perhaps no man in the whole country was better known. His name has been the synonyme for success. The story of his life, from the days when he was a poor emigrant boy to the years he has reigned a merchant prince, has awakened and moved many a young man to action. The incidents of his life are familiar to many, and yet they contain such proof of the earnestness of upright and honorable endeavor, that we are tempted to recite them again as his work has closed. He was born in Belfast, in 1808, and was liberally educated. He came to New York when he was 21 years of age and became a teacher. Soon afterwards his grandmother in Ireland died and left him a small legacy. Instead of bringing his little fortune back in gold he invested it in lace. With basket in hand he sought out the first families of the city, who could afford to buy his costly articles. His manners and modesty were such as to win for him the good will of some of his customers, who advised him to start a dry goods store. This advice he also followed and soon found a small store. The business prospered from the beginning, increasing so rapidly that Stewart found it necessary to obtain larger premises. He said at one time that he would not be satisfied until he increased his business so that his sales would amount to \$1,000,000 a month. By his strict integrity and straightforwardness his ambition was more than gratified, for in the year 1865 his sales amounted to \$55,000,000. Thus the basket peddler of lace went onward, by most careful attention to business, until he died possessed of a fortune of \$40,000,000. It was the result of honorable toil, sagacity and enterprise. The secret of his success was maintained throughout his whole career; it was—"Truth and Honesty."

DURING the month of March there were 7,133 arrivals in this city, and 3,310 departures. Of the arrivals, 2,799 were Chinese, making the total number of these people coming to our shores in three months, 5,400. The net gain in population for the quarter is 2,800 less than the corresponding period of 1875.

Gold and Silver Mining.

[By ALMARN B. PAUL.]

Of later years I have written more or less on the subject of gold mining, and endeavored to create a greater interest in this branch of our industries; but anything on the subject has been of little moment in the face of the grand hurrah for silver mining, which has carried the palm for capital for the past 15 years. The result of centering so much capital in one branch is before our business men every hour of the day, viz: 10 per cent. discount on silver coin, and from 15 to 20 per cent. on silver bullion.

If all the farmers of the State turn their attention to raising wheat, the market would soon become glutted, and wheat be at a discount, or what is the same thing, must lower its value. It is the same with silver now.

The "silver problem" is something to solve, says one. There is only one solution for it, and that is, we must produce more gold. A surplus of the precious metals, properly balanced, can but produce general good, in the increased value of everything but itself; but, while gold is the standard of value, it must be properly balanced by production, or discount of silver is the result. I need not say we must produce more gold; the silver evil, if so it can be considered, will bring forth its own remedy.

The discount on bullion is a fearful margin against silver mining, and at the same time is an equal percentage in favor of gold mining, and if the California press can appreciate the position of this metallic question, as it stands to-day, they will see an opening for giving renewed activity to every gold producing locality in this State, and in making California more attractive for capital than she has been for the past 15 years.

Gold mining, to-day, has 20 per cent. in its favor above what it had two years ago, and why should it not be more attractive? No business shows the same advance in its favor. California have given their energies and capital for the building up of Nevada and other silver producing localities; now suppose they throw some of their energies and their silver surplus into the building up of California through her gold mining interest.

In this question of silver vs. gold there is more than production to be cared for by the whole coast, and that is, that we do not let Congress out-legislate our business movements, and hence from us our gold currency, leaving us only the silver product for currency. This may seem at first blush to be impossible; but when the laws of trade, as relates to the precious metals, and especially as gold stands to-day, not only in the United States but Europe, it will be received as a proposition not to be lightly considered, but watched and acted upon. We must not be too much flattered by what is proposed in Congress to help us out on the silver question, but pay especial attention to keeping the gold ourselves, and discharging our silver products over the whole Union of States.

It would be a nice financial dodge of Congress and the financial heads of the Treasury and Eastern banks to force the discount on silver to a greenback basis and then give us, of this coast, the alternative of currency or silver, or both, while they quietly legislate and draw away our gold currency to pay for imports and duties, and on which they would make a handsome advance.

California has got to be watchful for maintaining gold as her currency, or we shall get beat in this metallic shuffle, even if Jones does lead the Senate on these questions—there are longer heads than his.

LANDS SOLD FOR DELINQUENT TAXES.—Governor Irwin signed the bill for the relief of persons whose lands were sold to the State for delinquent taxes under the act of 1874. The law now provides that where lands have become the property of the State under the delinquent tax law, the person originally owning the same, or his successor in interest, upon payment to the County Treasurer of the amount of the taxes, together with all the costs incurred, shall receive again a title to the land. An exception is made in this law that the parties shall not be entitled to recover land, originally owned by the State, where said lands were not paid for in full at the time of the delinquency.

IMPERIAL.—The articles of incorporation and also the certificate of consolidation of the Consolidated Imperial mining company were filed on the 12th inst. The consolidation includes the Imperial, Empire Mill, Consolidated Gold Hill, Eclipse, Winters and Plato Gold Hill Consolidated, Treach Gold Hill, Bacon and Bowers mining companies. The capital stock of the new company is \$50,000,000, divided into 500,000 shares of \$100 each. The purpose for which it is formed is to carry on the business of mining in all its departments, etc. The trustees are A. K. P. Harmon, J. D. Fry, A. C. Weller, J. H. Dohinson, Alphens Bull, William Norris and Joseph Sharon.

REDUCING FARES.—All the main line railroads throughout the United States, except the Union and Central Pacific, have agreed to sell tickets to Philadelphia and the Centennial at 25 per cent. discount.

THE MINERS of Staffordshire and several other mining districts of England and Wales are on a strike.

California Manufactures.

We were in one of our large city furniture stores the other day and as we passed from one floor to another, covered with the best specimens of the cabinet maker's art, we were assured repeatedly by the salesman: "There is not a piece of California made furniture in our whole establishment—every article is imported; we will not keep anything else."

We confess the words grated harshly on our ear. The furniture was most elegant and costly. The salesman doubtless emphasized the fact that it all came from the East, because he finds that our wealthy house furnishers prefer imported goods. Salesman are very acute men. They catch and employ in their trade what seems to be the disposition of the people. It is evidently "high-toned" to have one's house supplied with Eastern furniture, therefore every comer to the store is assured that the establishment will keep nothing made in this State.

This is not right. Our moneyed citizens, by frowning upon home manufacturers and paying much higher prices for imported articles, are crushing the industries of the State. They are throwing mud into the spring of their own prosperity. They are doing the State an injury by placing stumbling blocks in the way of its advancement. It will not do for our rich men to glory in our climate, in the richness of our mines or in the fertility of our fields, orchards and vineyards. It will not do to limit their patronage to the discoveries of nuggets and the production of mammoth vegetables and giant fruits. No; there must be patronage and encouragement bestowed upon our struggling home manufacturing industries.

There is now on the way to Philadelphia, a splendid display of California native woods for exhibition at the Centennial. The blocks are polished like mirrors. The richly grained and deeply colored woods will make Eastern workmen long for the chance to turn a tool into such fine material. Their ingenuity will sport in the fancy of what gems and glories of cabinets it could carve from these splendid forest growths. Suppose these workmen speak to their employers of such a thought. Laughing in his sleeve, the employing manufacturer will turn to the large figures of his California trade and say: "These trees would rot and you would starve, for rich Californians would not purchase your masterpieces. It is the fashion there to fill grand houses with my goods and I have their money here,—aha, here in my safe."

Californians, rich and prosperous, with princely mansions, overlooking bay and strait, proud in their eminence, you are doing your State an injury in this kneeling to a fancy which calls for Eastern goods. You are crippling home industry; you are forcing skilled laborers into tens when they ought to be counted by hundreds; you are placing limits to agricultural increase, because your policy cuts off markets to which it should minister. Your mansions are palaces, but—we had almost written, whited sepulchers, because the glory of the imported splendor which is in them is purchased at the cost of life to many home industries. You love your State, it has made you princes of wealth, and yet you disregard its needs in the disposition of your patronage. The burden of blame rests with you because you "set the style;" you dictate the disposition. The whole population mimics you. From the magnificence of your full furnishing, the fever dwindles according to each man's purse, until it ends in the imported footstool of the salaried clerk.

This is not right. Instead of hearing the hateful exclamation: "We keep nothing whatever of California manufacture," let the day speed when the proud manufacturer is able to say: "My workmen are the best in the world, everything we have is California manufacture."

MINING ACCIDENT.—The Virginia Chronicle of April 8th, says: Last Wednesday Edward Miller, a miner employed in the Consolidated Virginia mine, was severely injured by a blast while at work in the lower levels. He had charged and tamped the powder, and lit the fuse. Whether it was owing to the fuse being an exceedingly quick one, or the whole being improperly lamped is uncertain. He says that when he had lighted the fuse and retreated about four feet, he thought it had failed to ignite, and he turned to go back. Hardly had he done so when he changed his mind, but was too late. He had not turned his back before the charge exploded, fearfully mangle him.

THEY have been making it more than tropically warm for Col. Steinberger, at Samoa. Late advices received by the schooner *Ada May*, which arrived here on the 12th inst., give the impression that the downfall of the late Premier of Samoa was occasioned rather by the jealousy of certain foreign representatives than by any fault or misstep on the part of Steinberger. Considerable sympathy is felt for the ingenious and ambitious statesman of the cannibal islands in his adversity.

DISSENTING stockholders of the Leopard mining company have held a meeting, at which 11,850 shares were represented, and propose to investigate the affairs of the company and examine its books through a committee which has been appointed.

[Continued from page 241.]

within. This globe is suspended on hollow journals, and on its exterior surface are circular racks, B, which engage with the gear wheel, C, and the latter communicates with this hand wheel, L. By turning this hand wheel the globe is easily rotated. E is the furnace, the blast from which enters the globe, which is previously filled with ore and closed, through the water twee, F, which passes through one of the hollow journals. During the operation of roasting, the globe is constantly rotated, so that the ore within is kept in agitation, thus allowing the heat to pass through and act upon every part of its mass. The volatile products make their exit through the opposite journal, G, and entering the condenser, H, are condensed by a fine shower of water entering through the perforated diaphragm, I. In this way such materials are reduced so as to be easily removable; and at the same time, if precious metals be under treatment, such portions of the latter as would otherwise escape are caught and retained. From the condenser the blast passes, as shown, into the chimney.

It May Also be Used for Smelling Purposes.

The adaptation of the furnace for smelting purposes is easily understood from Fig. 3. The globe is of course held stationary during this operation; and the blast, entering by water tweers through both journals, passes down through the charge, is reflected up, and exits through the open man-hole above. The tweers can be continued downward and entirely around the bottom of the globe, if required. When the process is complete, the globe may be tipped to discharge its contents through the man-hole at J, or it may remain stationary and

The first one of these furnaces is being constructed by the Hartford Machine Co. for the new nickel smelting and refining works of Hartford, Conn. Four complete furnaces of like pattern are to be erected in these works. Patented April 6, 1875. For further information address the inventor, at 74 Asylum street, New Haven, Conn.

Gems and Precious Stones.

(Written for the Press by HENRY G. HANES.)

(Continued from last week.)

A.—Diamond, Jet and Cannel Coal.

Newton first suggested the probability of the diamond being combustible. He was led to this opinion by observing its power of refracting light so strongly. It was in 1675 that he advanced this theory. In 1694, the members of the Academy of Florence succeeded by means of powerful lenses in consuming diamonds. Lavoisier and others proved that the diamond was not evaporated, as supposed by the Académiciens, but was actually burned. Lavoisier found by his experiment that if air was excluded, no decomposition took place. He burned diamonds in close vessels with powerful burning glasses, and found that carbonic acid was produced, and discovered and announced the striking similarity between their nature and that of charcoal.

Sir George McKenzie found that they could be consumed in a common muffle. In 1797, Mr. Tennant made a decisive experiment by placing a diamond, the weight of which was noted, into a tube of gold with nitrate of potash. The tube was subjected to great heat, which was maintained some time. The diamond was

associated with a peculiar granular laminated quartz rock or sandstone, to which the name of itacolumite has been given. According to Dana it owes its lamination to a little tale or mica. This rock is found in Brazil, in the Urals, and in North Carolina and Georgia. The diamond is also found in a conglomerate called "casalho," which consists of rolled quartz pebbles in a ferruginous cement. Platinum, gold, rutile, zircon, quartz, feldspar, brookite, diaspore, magnetite and yttria minerals are almost always the associates of the diamond. Some platinum has been found in Georgia and North Carolina, where a few diamonds have been found.

Humboldt, in one of his works—"Essay on the Bearing of Rocks"—calls attention to the fact that gold, platinum and diamonds are associates in various parts of the globe; in some places, gold, platinum and palladium, in others, gold, platinum and diamonds. In the river Abote, in Brazil, diamonds are found with platinum; near Tejuca, with platinum and gold. These facts awakened in him the strongest hope of finding diamonds in the Ural, where the association of these metals is known to exist. When he arrived at any of the works, he caused the gold sands to be examined microscopically, and if gold and platinum were found, he directed the workmen to look carefully for diamonds. These examinations led to the discovery of microscopic crystals, previously unknown in the gold sands of the Ural—such crystals as in Brazil occurred with gold, platinum and diamonds.

The truth of Humboldt's theory as to the existence of diamonds in the gold sands of the Ural was proved by the subsequent discovery of a valuable stone by Paul Popoff, a boy of 14,

I believe Mr. Melville Attwood, of this city, was the first to predict the discovery of diamonds in California. I quote from a newspaper article written by him in 1854. He says: "I am anxious to call attention to the chance of finding diamonds in this country and the likelihood of their being overlooked. The rocks in which they occur are common in California. Itacolumite, a soft micaceous sandstone, always the associate of the diamond, is also found here. The gravel always found in the river washings so closely resembles the "casalho," or "diamond gravel" of Brazil, that I think it very probable that if proper search was made diamonds would be found." Mr. Attwood spent several years in the diamond districts of Brazil and is familiar with the subject of which he wrote.

Among other localities of diamonds on the Pacific coast I may mention North San Juan, Nevada county; French Corral; Forest Hill, El Dorado county; Tuttle town, Amador county; Cherokee Flat, Butte county; Owyhee river, Idaho.

In 1850 Rev. Mr. Seymour saw a diamond in California with curved faces, the size of a pea. It was light straw colored, such as have since been found at Cherokee Flat.

(To be Continued.)

ASSAYING.—Either somebody has been sold, or else metallurgy has achieved a great triumph. Now the facts are these, at any rate, a correspondent at Littleton furnishes the points and vouchers for their accuracy: Some gentlemen interested in the new discoveries on Deer creek, in the vicinity of Littleton, had numerous specimens tested by assay at the school of mines in this city. In every instance

Fig. II.

MANES' NEW REVOLVING FURNACE FOR TREATING ORES, ETC.

the charge be removed through the vent at K.

General Advantages of the New Furnace.

Many of the ores hitherto found most difficult to handle, such as nickel, cobalt, antimony, arsenic, zinc, etc., can be safely worked in this furnace, as no injurious fumes, save such as pass through the condensers, can escape.

The following are a few of the many important purposes, besides the treating of gold and silver ores, that the Manes revolving furnace can be practically used for:

1st. Making wrought iron direct from the molten iron of the blast furnace or cupola. Also, malleable iron castings that require no annealing and can be worked under the hammer.

2d. To make several grades of steel without the aid of crucibles, thereby saving the great amount of labor and expense now required for this purpose.

3d. Refining, alloying and mixing metals of many kinds; also, oxidizing lead and zinc very rapidly and at little cost.

4th. Extracting mercury, (or quicksilver,) antimony, arsenic, zinc, bismuth, cobalt, nickel, lead, copper and all other metals from their ores.

5th. Making gas from coal or other materials; also, coke and coal for smelting purposes; and the washing of coal and other minerals to free them from sulphur and other impurities.

6th. Distilling and purifying mineral and other oils.

7th. Rendering or extracting lard, tallow, or any other fatty matter.

8th. Mixing mortar and concrete for building purposes, laying of roads, etc.

This furnace can be used for a great many other purposes too numerous to mention here. It is destined to come into very general use throughout the United States and foreign countries.

A great amount of labor is saved by its use in all the various purposes for which it is so well adapted, and it is without question one of the most complete labor-saving inventions that has ever been brought before the public.

oxidized at the expense of the nitre, and was consumed. The carbonic acid evolved was conducted into lime water, and the precipitated carbonate of lime weighed. It was found to be equivalent to carbon equal to the weight of the diamond consumed, proving it to be pure carbon.

The diamond may be burned in oxygen by suspending it in a glass globe filled with that gas. The stone is held suspended in a coil of fine platinum wire, which is made red hot by passing a current of electricity through it. The diamond soon begins to burn, and is wholly consumed. Lime water or baryta water is then shaken in the globe, when a precipitate of carbonate of lime or baryta is formed, which dissolves with effervescence in dilute acids.

The diamond can be fused by the action of a powerful galvanic battery. Experiments made with a view to prove this resulted in the fusion of six small diamonds in seven and one-half minutes. On exposure to the greatest heat they first changed to charcoal, then to graphite, after which they fused into globules. These experiments led to the conclusion that the diamond is not produced by the action of intense heat on vegetable or organic substances, which is a favorite theory.

The diamond crystallizes in the isometric system; sometimes crystals show the impression of other crystals upon their faces.

The Indian diamonds are generally octahedral. Those from Brazil are generally dodecahedrons.

The diamond is a non-conductor of electricity.

After a great fire in Hamburg, diamonds were sold for small sums which had turned black, but upon being repolished they became again as brilliant as ever.

Black diamonds are sometimes called "carbonate," or "carbonado." They are even harder than the crystallized stones. They are found in mummillay masses, sometimes 1,000 carats in weight.

But few diamonds can be used for cutting glass. The best glaziers' diamonds are worth \$50 per carat.

The diamond is generally, if not invariably,

to whom belongs the honor. It was first supposed to be a topaz, but a young Freiberg student, a Mr. Schmidt, who had the necessary instruments to test the hardness and specific gravity, identified it as a true diamond. Two others were soon afterwards found, the third being larger than both the others, followed by systematic search, which has since produced many valuable stones.

The same association of metals occurs in the northern counties of California, especially in the region drained by the Trinity river, in the sands of which microscopic diamonds are actually found. The same may be said of the vicinity of Coos Bay, in Oregon, and along the banks of Smith river, in Del Norte county. Miners throughout this whole region should search carefully for diamonds, and should send anything they find, which is likely to be such, to some competent and reliable mineralogist for identification. Diamonds may be looked for in flumes and in cleaning up sluices, with gold and platinum. An examination of the platinum sands of the Trinity river was made by Prof. F. Woehler, of Göttingen, who found the presence of diamonds in them. After removing gold, platinum, chromic iron, silica, ruthenium, etc., by the usual methods, he examined the residue microscopically, and observed colorless, transparent grains, which he presumed to be diamonds. Subsequent combustion in oxygen and precipitation of solution of baryta by the carbonic acid evolved, convinced him that the microscopic crystals were true diamonds.

This fact is an extremely important one to the inhabitants of the Pacific coast.

Diamonds Have Been Found

At Volcano, in Amador county, in a peculiar volcanic formation, described by Prof. Whitney as "ashes and pumice cemented and stratified by water." The crystals had the form of the icositetrahedron, with faces curved in the manner peculiar to the diamond. These facts and the discovery of Prof. Woehler lead to the assumption that diamonds are likely to be found with the gold of California and Oregon, and may become an important object of search.

the returns were encouraging to the mine owners. They must have doubted the genuineness of the mineral, or the metallurgists, or something, for as this correspondent admits, they bought a sycle stone of Jensen, Bliss & Co., of Denver, pulverized it and left it at the school of mines to be assayed. What representations accompanied the package of pulverized sycle stone, deponent, or correspondent sayeth not, but it was presumably represented to be specimen material from the new mines. However that may have been, the practical jokers got a certificate, No. 696, testifying that the stone yielded \$6 in gold and \$15.48 in silver! This isn't very strange, after all. Somebody—De in Swift or somebody else—says that sunbeams may be extracted from cnumbers, but the process is tedious. If an assayer can't extract a little gold and silver from a sycle stone, or, for that matter, from a brickbat, monkey-wrench, or buffalo chip, what is his calling worth to him?—*Denver News*.

A NEW MILL FOR TUSCARORA.—Mr. J. T. Babcock, of this city, is now arranging for the erection of a 20-stamp mill, which he will put up immediately on a mine in the Tuscarora mining district, about 30 miles this side of Cornucopia. The company engaged in this enterprise is known as the De Frees mining company. Their business office is at room No. 9, Halleck's building, in this city. Mr. Babcock is a stockholder in the mine, as well as the contractor for putting up the mill. The mine is a very promising one, and has been opened by a shaft 200 feet deep, with lateral drifts on the ledge, each way, a distance of 100 feet. About 350 tons of ore are already on the dump, the average assays of which indicate that the rock will pay, by milling, about \$100 to the ton—silver and gold. There is no base metal in the ore, which consists largely of chlorides. The ledge increases from three feet in width at the surface to eight at bottom of shaft. The contractor expects to have the mill running in about three months.

Nevada County Copper Mines.

Our county is known and acknowledged to be the richest gold mining section in the State. It also gives promise of excelling in the production of copper. That metal has been known to exist in the southern part of the county, near Spenceville, for a long time. In the winter of 1862-3, prospecting was commenced there, and a great excitement followed. Some of the ledges were sold for \$100 per foot. A large number of ledges were discovered, and a great deal of prospecting was done on them. For want of experience in working this kind of ore, or for the lack of the proper machinery, the mines did not pay and work was abandoned. Work on the ledge now owned by the San Francisco copper mining company, has, however, been going on for some years, and at the present time everything is looking favorably again, and the copper regions are beginning to attract the attention of capitalists and practical miners. We learn from I. J. Rolfe, who visited the mine this week, the following interesting particulars. The ledge has been sunk on to a depth of 150 feet. It is 80 feet in width, though of low grade ore, (averaging from eight to 12 per cent. copper) and can be worked at a very satisfactory profit. It costs one dollar per ton to mine and raise the rock to the surface, and six dollars covers the entire expense of mining and reducing the ore to bars ready for shipment. The ore is first roasted, and then put through the leaching process. There are four tons of pure metal now on hand ready for running into bars for shipment. The capacity of the works will be greatly enlarged this summer, so that a ton of copper can be obtained in 24 hours, after the improvements are completed. Mr. C. H. Aaron is the present superintendent of the mine. Bitner & Canfield have a mine about a mile and a half this side the San Francisco company's, which is smaller but much richer, and machinery having been put upon it the past year, it is now ready for work. The rock in this mine is crushed and then roasted by a method similar to the chlorination process. D. O. Mills & Co. also have a ledge near by, upon which machinery will be erected this season. The rock in this mine went from 20 to 25 per cent. pure copper, years ago. The ledge is about 12 feet thick. Machinery will be put up this season. Altogether the copper interests at Spenceville are looking up, and indications now point to very flourishing times in that section of the county from this time forth.—*Nevada Transcript.*

To ENCOURAGE EXTEMPORANEOUS SPEAKING, the seniors of Cornell university are now required to deliver short extemporaneous speeches on literary subjects in place of written essays.

IMMENSE deposits of copper ore have recently been discovered in Socorro county, New Mexico.

BERRY & PLACE,

San Francisco,

Are the only Agents for sale of these Engines in the Pacific States.

Hoisting Engines. Mining Engines.

COOK, RYMES & CO.'S celebrated Hoisting Engines have been too long in use on the Pacific coast to require any special recommendation from us. They are well known from Alaska to Mexico. We would refer with confidence to any one of the hundreds in use. They still sustain their old reputation, the manufacturers not having followed the now too common practice of reducing the quality of material and workmanship to compete with cheaper engines. They have lately been greatly improved by adding large drums, and reverse motions.

MINING HOISTING ENGINES.

(Manufactured by the same parties.)

Our new Mining Engine is built from plans and specifications of several of our most successful mining engineers, and the result is the most complete

Double Drum Hoisting Engine

ever built. Their advantages will be seen at a glance by any one familiar with the necessities of a mine. These engines may be seen in use in Ophir, Con. Virginia, Chollar, Europa, Niagara, Leviathan, Phil Sheridan, and several other mines on the Comstock Lode. For sale only at

ANGELL'S CHARCOAL DENTAL SOAP
for Whitening and Preserving the Teeth. J. W. ANGELL, Prop., San Francisco.

"The Public Lands of California."

The demand for this new work is steadily increasing, and the more widely that its merits are becoming known, its usefulness to everyone is becoming more fully demonstrated. The map of California and Nevada alone is worth more than fifty cents, the price asked for the work, and the fact that a glance at its pages shows the leading products, population, etc., of each county in the State, besides a list of the surveys of United States Land, subject to the homestead and pre-emption laws of Congress; a correct copy of the laws of Congress in regard to locating and holding this land, etc., renders it of inestimable value. Orders sent to Dewey & Co., enclosing fifty cents, will meet with prompt attention, as it will be forwarded immediately post paid.

To Mining Companies.

A Mining and Civil Engineer of long experience, well acquainted with the superintendence of mines and mills, the projecting and construction of hydraulic works, machinery, etc., is open for re-engagement. Apply to Messrs. Dewey & Co., of the Mining and Scientific Press, 224 Sansome street, San Francisco, for reference, or to J. B., Postoffice Box 633, Oakland, Cal.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

DR. J. T. JOHNSON—California and Nevada.

Thanks for Prompt Attention.

STOCKTON, June 26, 1875.

Messrs. Dewey & Co., S. F.—
I have received the patent for my invention in wagon brakes, which you procured for me; patented May 11, 1875, No. 163,046. Thanks to you for your prompt attention to the case; you will hereafter be my attorneys in such cases. I recommend all inventors on the Pacific coast to give you a call, which I think they will never have any cause to regret. Very truly yours,
GEO. G. BOCKLAND
Stockton, Cal.

SANTA CLARA, CAL., April 6th, 1875.

Messrs. DEWEY & Co., Gents.—We have just received Patent No. 160,535, for J. T. Watkins & Co's Mammoth Road Grader, which was patented through your Agency. It is the newest and best that we have ever received. We feel proud of it and thankful to you for the care and attention that you have given it, and when we have anything to do in that line of business we will surely give you a call. Very respectfully,
J. T. WATKINS & Co.

ROASTING OF GOLD AND SILVER ORES, and the Extraction of their Respective Metals without Quicksilver. 1870. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. Price \$2.50 coin, or \$3 currency, postage free. Published and sold at this office.

CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1877. The most complete treatise. Published at this office. Price \$5, post-paid.

THOUGHTLESSNESS.—Persons sometimes return their paper, marked "stop this paper." Their name being pasted on the sheet they think that is all we need to be able to cross their names off. Now that is thoughtlessness. Your P. O. address is needed as much as your name. We have thousands of names arranged only according to locality. Our mailing clerk does not know where everybody lives.

BE MOORE PARTICULAR.—We can only make the changes requested by the following parties on our mailing list, when they, or some one else, send us their P. O. address. Otherwise we would have to look over from 7,000 to 10,000 names. Frank Becker, O. Seawell, L. Boyer, M. Lewis, F. Anson, and Antonio Byrnes. We also want the address of Wm. Buck.

SUBSCRIBERS are requested to examine the printed address on their papers. If mistakes occur at any time, please report them to this office. The last figures (at the extreme right) represent the year that your subscription is paid to. Next to these the day and month is represented. For instance, your subscription being paid to July 4th, 1876, it would be represented, viz: j1 4 76; or j175.

SUTTEE CREEK, February 26th, 1875.

Messrs. DEWEY & Co.—I have received my Letters Patent through your Agency. And, for your promptness, accept my thanks. Yours,
S. N. KNIGHT.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

California Acclimatizing Society—Location

of principal place of business, San Francisco, Cal. Notice is hereby given, that at a meeting of the Board of Directors, held on the seventh day of April, 1876, an assessment (No. 7) of fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, room 37, Nevada block, No. 309 Montgomery street, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the seventeenth day of May, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the seventh day of June, 1876, to pay the delinquent assessment, together with costs of advertisement and expenses of sale. By order of the Board of Directors.

Office, room 37, Nevada block, No. 309 Montgomery street, San Francisco, Cal.

The California Watch Company—Location

of principal place of business, No. 120 Sutter street, San Francisco, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment levied on the eighth day of March, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't.
M Godley, trustee.....	1	3,000	\$15,000 00
A Rammelsberg, trustee..	2	200	1,000 00
A Rammelsberg, trustee..	3	100	500 00
T M Antieil.....	4	10	50 00
A Rammelsberg, trustee..	5	1,130	5,650 00
Paul Cornell.....	13	10	50 00

And in accordance with law, and an order of the Board of Directors made on the eighth day of March, 1876, so many shares of each parcel of said stock as may be necessary, will be sold at public auction at the office of the company, on the first day of May, 1876, at the hour of twelve o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

H. T. GRAVES, Secretary. Office, No. 120 Sutter street, room 10, San Francisco, Cal.

Eureka Stone Manufacturing Company—

Location of principal place of business, city and county of San Francisco, State of California.

Notice is hereby given that at a meeting of the Board of Directors, held on the eighth day of March, 1876, an assessment (No. 4) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 567 Market street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fourth day of April, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on the eighth day of May, 1876, to pay the delinquent assessment together with costs of advertising and expenses of sale.

P. D. MOWELL, Secretary. Office, No. 567 Market street, San Francisco, Cal.

Klamath Quartz Mining Company—Location

of principal place of business, San Francisco, Cal. Location of works, Liberty township, Siskiyou county, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment levied on the second day of March, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
E A Richardson, trustee....	44	500	\$1500 00

And in accordance with law, and an order of the

Board of Directors, made on the second day of March, 1876, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the company, room 8, No. 315 California street, San Francisco, Cal., on Tuesday, the second day of May, 1876, at the hour of one o'clock, P. M., of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale.

J. F. NESMITH, Secretary. Office, room 8, 315 California street, San Francisco, Cal.

The Golden Sun Gold Mining Company.

Location of principal place of business, San Francisco, Cal. Location of works, Forks of Butte Mining District, Butte county, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1), levied on the first day of March, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

And in accordance with law, and an order of the Board of Directors, made on the first day of March, 1876, so many shares of each parcel of said stock as may be necessary, will be sold at public auction on the 24th day of April, 1876, at the hour of two o'clock, P. M., at the office of the company, 702 Market street, room 2, San Francisco, Cal., to pay said delinquent assessments thereon, together with costs of advertising and expenses of sale.

JOS. PENTECOST, Secretary. Office, 702 Market street, San Francisco, Cal.

Josephine Gravel Mining Company—

Location of principal place of business, San Francisco, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the twenty-third day of February, 1876, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.

Improved and Successful Method of Sinking Shafts.

The *Colliery Guardian*, under date of London, England, November 19th, has the following:

In our last issue we stated that the directors of the Cannock and Huntington colliery company had decided to adopt the Chaudron process for the sinking of the pits at Huntington, and that some of the directors, accompanied by mining engineers, had visited Belgium and the North of France for the purpose of inspecting the pits sunk and sinking under the patent. The party first visited Briony, where a pit had been sunk, and was then being lined with tubbing. From thence they went to Marles, where one pit had been completed and another was in course of sinking; and from thence to Mons, where pits were being sunk. At all these places the visitors were impressed with the extreme simplicity of the work and the perfect character of the arrangements. The pits at Mons were very wet, the water lying within a yard of the surface.

Under M. Chaudron's process no water is drawn during the sinking, and if the sides do not stand, light lining tubes are put in. Very few hands, it is stated, are required in the work, eight or ten men being sufficient for all purposes, and the machinery is calculated to go through any ground, from running sand to the hardest rocks. All the sinkings visited were through chalk measures—occasionally through seams of solid flint, but the powerful machinery breaks through everything; and the spoon, which is estimated to hold from five to six tons, is let down, filled by a self-acting apparatus, drawn up, and emptied with as little trouble as an ordinary bucket. Twenty-eight pits have been sunk under this system at depths varying from 300 to 450 yards, including some requiring 250 yards of tubbing, and the system has not failed in a single instance. The tubbing is not in segments, as in England, but is cast in solid pieces of any diameter required, and five feet high, with flanges. Sheets of lead are passed between each casting, and each securely riveted to its neighbor.

After going down all the pits, which were sufficiently free of water, and carefully inspecting the tubbing, which was fixed or in course of fixing, the directors visited the foundry at Chateau Lineau, where the tubbing is made, and where they saw it cast, and tested with a strain of 420 pounds to the square inch. The result of the visit was to satisfy the whole of party that the sinking by the Chaudron process is more certain, speedy and economical than any plan now adopted in this country, and that the tubbing used by M. Chaudron is vastly superior, safer, and cheaper than that used here.

DRILLING MACHINES.

PORTABLE DRILLS. Driven by power in any direction, self-feed and convenient adjustment.

RADIAL DRILLS. Self-feed—large adjustable box table—separate base plate, every convenience.

VERTICAL DRILLS. Self-feeding—of new and improved designs.

MULTIPLE DRILLS. For boiler work, etc., 2 to 20 spindles, fed and returned by power or hand, together or separately.

HORIZONTAL BORING AND DRILLING MACHINES. For large pieces—with boring head, adjustable, vertically and horizontally.

SPECIAL DRILLS. For special work. Gun Blank Drills, Coal Drills, &c., built to order.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."

HERCULES POWDER.

HERCULES Slaying the Giants.

[Hercules, the son of Jupiter and Almena, was descended directly from the Gods. He performed more wonderful deeds of strength than any of the heroes of old. On one occasion, he was sent by Eurystheus to execute a very great task, when he found himself opposed by several Giants, among whom were the powerful Giant Geryon, Eurytion, a Monster with three heads and six arms, and the two-headed dog, Orthus. All these he slew with his club. He then came to a high mountain, which, with one blow of his club, he broke from summit to base, and thereby made an entrance into the Mediterranean Sea, through the Rock of Gibraltar, the Straits of which are known to this day as the Pillars of Hercules.]

We wish to call the attention of Miners and others to a few points of the superiority of **Hercules Powder** over all other strong Explosives:

1. Its strength is greater than that of any other in use. The materials of which it consists are compounded upon strictly scientific principles, and are not a simple neutral absorbent employed that will hold a quantity of Nitro-glycerine. It is the opinion of the best chemists to whom the matter has been submitted that no mixture has been employed that so thoroughly promotes the whole tremendous force of the explosives employed, and at the same time neutralizes the offensive gases caused by the explosion. With this powder one-half the time is saved that is lost by using any other strong Powder, before you can resume work after a blast.

2. **UNIFORMITY.**—The materials of the mixture are chemically prepared, and therefore, great uniformity can always be depended upon and the best results obtained. This is a great advantage over any that varies in its strength as those must which are mixed with any natural earth.

3. **SAFETY.**—So perfect is this mixture that no accident can happen with it from premature or accidental explosion, if persons will half follow the rules laid down for its use. No Powder has ever been invented where so few accidents have happened with it in proportion to the quantities which have been used.

4. **CARTRIDGES.**—It is well known that nitro-glycerine has a tendency to decompose by volatilization. These are the "fumes" that are smelled on going into a close warm drift, or room where nitro-glycerine powders are stored. To prevent the escape of these "fumes" an almost hermetically sealed cartridge is employed, and so effectually is it, that some cartridges filled with Hercules were exposed to a blazing California sun for six months in summer, with no perceptible loss of strength. This is a great advantage over the open porous paper generally used for cartridges.

5. **ECONOMY.**—We believe that any miner who will take the trouble to investigate the matter will satisfy himself that full 15 per cent. is saved by using the HERCULES over any other strong Powder manufactured.

Query. Is this worth saving? We should think so. Try it. { Hercules X X No. 1, for extreme hard rock.
{ Hercules X X No. 2, for medium hard rock.

The GREAT SUCCESS of the HERCULES POWDER naturally aroused a strong opposition to its use, and litigation in defense of its rights become necessary. We would therefore call the attention of the public to the FINAL DECISION in the U. S. Circuit Court of the whole matter in favor of the California Powder Works, *which explains itself*:

DECISION OF THE COURT.

At a stated Term of the Circuit Court of the United States of America of the Ninth Judicial Circuit, within and for the District of California, held at the Court Room thereof, in the City and County of San Francisco, on Wednesday, the sixth day of October, A. D., 1875.

Present.—Honorable Stephen J. Field, Associate Justice of the U. S. Supreme Court, Honorable Lorenzo Sawyer, Circuit Judge.
THE GIANT POWDER COMPANY vs. THE CALIFORNIA POWDER WORKS, Et AL., In Equity, No. 1,233.—The Court having, on the 22d day of September, A. D., 1875, being a day in the July Term, A. D., 1875, of said Court, sustained the demurrer of the defendants to the complainant's amended Bill of Complaint herein, will leave to complainant to amend its said bill on or before the next succeeding rule day, and the said time granted complainant within which to amend its said bill having expired, and the default of said complainant to amend its said bill having been duly entered, and the Court having on the sixth day of October of the said term and year, on motion of C. R. Greathouse, Esq., Solicitor for defendants, M. A. Wheaton, Esq., Solicitor for complainant, being present, in open Court, and declining to amend his said bill of complaint, he having elected to abide by his said bill of complaint as filed in this cause, ordered that a decree be entered herein dismissing said bill.

Thereupon, upon consideration thereof, it is ordered, adjudged and decreed, that the complainant's said bill be, and the same hereby is dismissed, and that the said complainant pay the said defendants their costs in this behalf expended.

October 15th, 1875.

ENDORSED.—Filed and entered, October 18th, 1875.

(Signed) LORENZO SAWYER,
U. S. Circuit, Judge Ninth Circuit.

L. S. B. SAWYER, Clerk.
By J. F. O'BRIEN, Dep. Clerk.

SAN FRANCISCO, SATURDAY, APRIL 22, 1876.

VOLUME XXVII
Number 17.

The Industrial Depression.

The present industrial depression is not confined to the United States, and it has been suggested that the revulsion in this country is but a part of the general ebb in the world's affairs everywhere. Numerous and large failures are constantly being reported in England. A report was lately made of twenty English firms, in the cotton and iron trade, whose deficits ranged all the way from \$140,000, the lowest, to \$15,000,000, the highest. The fact that money can be borrowed in England at the low rate of three per cent. per annum, indicates that the trouble arises from a want of confidence and not a lack of money.

A recent issue of a late leading German journal complains of the unfavorable condition of trade in that country also, and attributes the result to the depression in the coal and iron trade, and the general increased cost of production, which prevents the accumulation of capital, and retards industrial development. France is, perhaps, the only European country which may at this time be considered in a prosperous condition.

Probably the chief cause of the present general depression arises from the recent disturbances in international trade throughout the world, brought about by the late Franco-German war, and the unsettled labor condition and advanced price of coal in England. The disarrangement of the labor market and coal trade of England, and the persistent efforts of her workmen in opposition to the introduction of labor-saving machinery, has so advanced or kept up the cost of production that her foreign trade has greatly fallen off, in consequence of which many of her heavy manufacturers and merchants have been seriously crippled or forced into bankruptcy. The good credit and supposed ample facilities of reputed wealthy firms enabled them for a while to float immense debts and be bankrupt for years before the public became aware of the fact—but after awhile confidence became shaken, distrust arose, and the panic, which yet exists, followed. And now, although money is so abundant there as to be freely offered at three per cent. on approved security, so little confidence exists that business security cannot be found, and the money lies idle in the Bank of England, while the laborers throughout the realm are clamoring for work to keep themselves and families from starvation—and there is but small hope of any early change for the better.

The people of this country are also still suffering from the results of our late war. The immense national debt thereby heaped upon us, together with the almost universal demoralization of public officers, indirectly brought about by the war (for war always demoralizes), is now weighing us down with taxes to such an extent as to almost paralyze industry. To this may also be added a vicious system of currency, which, if not expressly designed, is at least admirably calculated for and industriously applied to making the rich richer and the poor poorer. With all these disadvantages, however, we are on the sure road to wealth and prosperity. Our lands are productive beyond measure; our manufactures are rapidly increasing and finding their way more and more into foreign markets; our mines of precious metals are astonishing ourselves and the world with their extraordinary riches; our exports of merchandise and agricultural products are increasing and our imports decreasing so rapidly that, to all appearances, the balance of trade will soon be in our favor; and now a thorough reform in national and financial relations, which will give us such an honest and economical administration of government as will reduce taxation to its proper standard, and furnish a currency in the interest of the people instead of money lenders, is all that is needed to dispel hard times from our midst and place this people directly on the high road to national and individual prosperity. The power to bring about this result the people have in their own hands, and the signs of the times fully indicate a determination on their part to use it, and that, too, truly and effectually.

With a proper administration of our governmental and monetary affairs, this country may soon become the workshop and granary of the world, and the almost sole producer of the precious metals.

Ore Feeders.

We don't presume that all of our readers are miners, and many that are not do not fully understand what is meant when we refer to various parts of mining machinery by their miners' names. For instance, how many persons would be puzzled if they were asked to define a winze, a horse, a buddle and numerous other crooked terms used by miners to represent miners' notions. We have headed this article "Ore Feeders," and lest some unsophisticated reader should infer that we refer to a class of "ani-

AUTOMATIC ORE FEEDER.

mata" that live and fatten on indigestible ore, we will explain that an ore feeder is a machine that is placed in front of a battery, and that it consists of a hopper, marked D, into which the ore is poured after it has been reduced to the desired size by passing through a rock breaker or crusher. Below this hopper is an inclined shute or table, E, upon which the ore will fall as it passes through the lower opening in the hopper. This table or shute is so arranged that when it is rotated or agitated the ore will be caused to drop from its edge into the battery under the stamps, as will be readily understood from the engraving. The amount of ore thus supplied to the battery is regulated by the stamps themselves, by means of a lever, B, one end of which is either attached to the shute or to a device which rotates the table, E, while its

opposite end extends out beside the stamp stem, H, the fulcrum being at or near the middle of the lever. A collar or tappet on the stamp stem is arranged to strike the end of this lever when the stamp drops close to the die, but when a sufficient quantity of ore is under the stamp to prevent the collar or tappet from dropping low enough to strike the end of the lever, the table is not agitated and the feed of the ore ceases. It will thus be seen that the machine is automatic in its action; that is, the requirement of the stamps is indicated by the amount of drop or force of the blow delivered by the tappet, and the amount of drop is regulated by the requirement of the stamps.

Before the introduction of automatic ore feeders the work was done by hand and the constant attendance of a man was required in order to prevent the stamps from getting out of material to work upon, otherwise the stamp would pound upon the die and damage would likely occur. Hand feeding, also, is less effective than machine feeding. A battery fed by an automatic ore feeder will crush fully one-third more ore in a day than one fed by hand, because with an automatic feeder the quantity supplied to the stamps is uniform—that is, the feed never exceeds the proper bounds, and never allows the supply to get so low as to permit the stamp and die to come together.

Automatic ore feeders have been known and used for many years. We believe they were first used in Mexico, but the early ore feeders were quite ineffectual for several reasons. First, they had no arrangement for regulating the feed according to the quality of ore. One carload of ore may be dry and composed of good sized pieces; this ore will feed freely, less motion of the shute or table being required to feed the desired quantity; while the next carload may be fine and wet, so that a greater amount of motion is required to force the ore forward into the battery. Secondly, the motion given to the shute was a shaking motion, which was not certain in its action, and sticky material would not leave the shute. Subsequent improvements, however, have provided a regulating device by which the motion of the feeding table or platform can be regulated by simply turning a screw without stopping the action of the feeder. Positive movements have been supplied for operating the table or shute. Sorapere are used for ensuring a positive feed when wet and sticky ore is to be fed, and taking it altogether, as the machine is now manufactured and used, it is

one of our great labor-saving and useful machines.

BILL TO UTILIZE PRODUCTS OF GOLD AND SILVER MINING.—A bill to utilize the products of gold and silver mining in the United States has been introduced by Mr. Banks; it provides that the Secretary of the Treasury shall establish in the great mining districts of gold and silver additional depositories and refineries, and receive from the miners and owners gold and silver, to be coined upon certificate of the Government assayer, and issue certificates of deposit therefor, payable to bearer and for such sums as the depositors may desire, and, when issued for more than \$500 in one certificate, to be made payable to order. Each certificate shall promise a return of the amount of gold and silver called for by the certificate, and shall be a legal tender in all transactions. The Government is to be liable for the safe keeping of gold and silver, and may become the owner thereof by obtaining certificates through purchase or redemption. The Secretary is also authorized to issue similar full value certificates on coin that is now, or may hereafter be, in the Treasury, reserving coin for redemption.

INVESTIGATIONS and compiled statistics show that only one railroad passenger in 7,000, 000 is killed, and only one to 1,500,000 is even so much as bruised. In the year 1874 only one person was killed on all the Massachusetts railroads, while 76 were killed by accidents in the city of Boston.

Explosions in Mines.

The terrible destruction of human life from explosions in coal mines has long been a matter of serious consideration, and various have been the appliances and precautions devised by scientific men to avoid or materially reduce the danger. The Davy lamp seems to afford very little protection, either from defects in its construction or carelessness in its management. Indeed, so unsafe or uncertain has it become that it has been seriously proposed to lay aside that lamp altogether, and go back to the use of naked lights as the less dangerous of the two.

This matter came up for discussion at a recent meeting of the French Academy of Sciences, at which meeting M. Faye read a paper in which he advocated the abolition of the Davy lamp and the substitution of uncovered oil lamps placed about 10 yards apart in the mines. By this means, he said, the explosive gases would be consumed gradually as they escaped, and without accident, just as a ton of powder would be got rid of harmlessly if exploded in pieces. In the discussion which ensued it was demonstrated that this project would not answer, as the deleterious gases, when escaping, would remain inert until they bore an explosive proportion, about eight per cent. to the atmosphere, in the same way as an ordinary gas jet if turned on in a room containing a light would not inflame, though an explosion would ensue when a sufficient quantity of the gas had mingled with the air.

M. Faye was ultimately induced to withdraw his paper. The members present generally testified to the efficiency of the Davy lamps if kept in good repair and used by careful miners; but, on the ground that these desiderata appeared to be unattainable, M. Boussingault gave his entire support to their abolition and the substitution of electrical lighting apparatus, as a means of reducing the excessive cost of the latter could be devised. In the course of the discussion reference was made to the method established with respect to the Davy lamp by M. Boussingault in the petroleum mines in Alsace. Before the miners enter these mines the efficiency of their lamps is tested by plunging them into a cylinder containing a petroleum vapor. The slightest flaw is detected.

AN INTERESTING DISCOVERY.—We see it stated that Prof. Silliman, of New Haven, has discovered a method of producing a peculiar physical change in German silver, Britannia metal, pewter and other like alloys, by a process which he has patented. This discovery seems to have been a natural outgrowth of the late discovery in tempering glass, which produces such an important and wonderful change in the constitution of that material. Prof. Silliman's discovery consists in exposing articles formed of any of the alloys above mentioned to the action of a regulated temperature, somewhat short of their melting point, in a bath of oil. After a little time, instead of giving out when struck a dead sound, they appear to have acquired the property of ringing clearly. This is no doubt due to a re-arrangement of the molecules of the alloy, which assume more of a crystalline structure than that which the alloy previously possessed. The discovery will no doubt find some valuable applications in the arts.

PATENT LITIGATION IN ENGLAND AND AMERICA.—Under the present patent law of Great Britain, patents are granted for every new idea for which any person may chance to apply and no questions asked as to who is the inventor. No official examination is had. To the average American mind it would appear that such a course would lead to endless litigation; but such is far from being the case, as from a recent report it appears that an average only of eight patent cases per annum are litigated in Great Britain, while the average in this country exceeds 10,000. It would appear from this fact that excessive legislation is a great stimulus to litigation.

New machines for the preparation of flax fiber have been invented, which it is claimed promise to produce as great a revolution in the flax production as was produced by the Jacquard loom and the cotton gin.

CORRESPONDENCE.

A Winter Visit to Mammoth Cave.

EDITORS PRESS:—Some account of a visit to Mammoth Cave in winter may be acceptable to your readers. By the railroad between Nashville and Louisville you reach Cave City, a station nine miles from this greatest of caverns. The travels by which life's work tosses us to and fro in diverse places, having carried the writer by this route three times without his taking the leisure to examine that really great "wonder of the world," he concluded it would be almost inextensible to lose the fourth opportunity, so he devoted a day, the 5th of January, in this Centennial year, to the long wished for visit. During the months when tourists usually go to see this cave, a brisk drive of two hours will easily take you there, over the limestone hills which abound in all this part of "Old Kentucky." But over the muddy roads of winter you do well to reach it in less than three hours. Almost the entire road is through a rolling country among miniature mountains, which in places must reach a height of 300 or 400 feet above the general level.

Well Improved and Fertile Farms

Are dotted quite thickly along the road, as many as ten being sometimes in sight in one small valley between the hills. A farmer of course surveys these with interest, as he hurries by. He observes that almost every farmhouse is constructed of neatly hewn oak logs of small size, usually eight or ten inches in diameter, and so nicely "chinked" and plastered as to make the walls outside even smoother than a weather-boarded house. The weatherboarding, when seen here, and nearly all the planks, indeed, are poplar. You must know that not a single pine is seen in all this region of oaks, and chestnuts and elms and poplars. What pine timber you see is brought from a great distance, and is more expensive than the native woods. Still, the hills are heavily timbered, though the trees are comparatively small. A few dwarfish cedars occasionally appear.

In several fields the corn had not yet been gathered. What wheat I saw was looking well. Here they sow both winter and spring wheat. This reminds me that in my letter written you while passing through Nebraska, your printer's "devil," or some kinsman of his, made me say that they sow no grain but rye in Nebraska. Now what I said, or meant to say, was that they sowed no grain but rye in winter there. Other small grains they sow in spring. But no! for

Mammoth Cave.

During the last two miles before you reach the Cave hotel you observe that no more farms appear. The forest is as wild as in the days when Daniel Boone first explored these regions, except that here and there some firewood has been cut. On inquiry, you learn that 2,000 acres were long since bought up around the mouth of the cave by its owners to prevent the possibility of having another entrance found, and a competition established in dealing out this wonder of Dame Nature. That there is good reason for this precaution is evident from the well known fact that the opening through which a white man first entered and discovered it in 1809, following to it a bear that he was hunting, is a quarter of a mile from its present large and convenient mouth. This first entrance is now closed.

To enter the cave you follow your guide down a winding pathway into a deep ravine thickly studded with forest trees, the natural growth, along its sides and bottom. At last you face the rocky chasm, and to reach the level of its floor, you descend to the right some rough steps made in its limestone formation. Just to your left, as you approach the dark month, a tiny stream of pure water dashes over the low cliff, and loses itself in crevices which lead it underground by some unknown channel. Just inside

The Entrance,

And protected from the breeze of the outside world, your guide lights his lard-oil lamps. These are suspended by a simple wire frame, but are not "safety lamps," for no explosive gas has ever been found in any of the hundred miles or so of avenues, chambers, domes, pits, etc., in Mammoth Cave.

Properly equipped with four of these, the guide and I made our lonely entrance. In summer he frequently leads in a dozen, or occasionally fifty tourists at a time. The one with me, a faithful negro man, kindly remembered by all who meet him, has performed this duty for the past 37 years. Soon our way was stopped by a solid stone wall and door of iron bars securely locked. Through this door a slight current of air was passing steadily from the cave. The average temperature of the air inside is 59 deg. Fah. Consequently, in warm weather the current flows out, in cold weather it flows in. The guide looked the door again when we entered, and we were at once, but for our lamps, in that darkness most profound, which continues through all this somber, weird journey, in regions that seem like the realm of the dead, a symbolic Hades truly.

For a short distance the flat limestone roof is but a few feet above your head, though the width of your pathway is full 20 feet. Soon the height of the roof increases, until it is supposed to be in places full 60 feet above you. First, your attention is attracted by a faint chattering sound, which you find comes from thousands of common bats, that are seen clinging singly or in large patches to the walls. In the first half mile of the cave myriads of them make their winter quarters. Their chirping is the only sound you hear during the whole route, except your own voices, or the dripping of water in the vicinity of Lethe, the Styx and Echo river. Indeed, these bats are the only inhabitants of the cave, except a few pale-colored crickets, near the two springs, a few rats of a dingy white color, and the curious blind fish of Echo river. Of the latter I examined a living one, in a glass jar, at the Cave hotel. It was of a light flesh color, and so translucent that you could easily distinguish its backbone, and some of its vitals. Yet it was in a plump, healthy condition, although I was assured that it had been three months in the jar, without any food. They merely change the water daily. The specimen examined was five and a half inches long.

About a quarter of a mile from the mouth of the cavern you find

Several Niter Vats.

Which were used to manufacture saltpeter for our powder mills during the war of 1812. Many small oak logs still remain which were bored and used as pipes to convey water to and from the vats. Though they have been lying in the cave for more than 60 years they are still in a remarkable state of preservation, some being as sound, to all appearances, as when they were placed there. For a quarter of a mile you find a line of these oak pipes, and then come to a second set of tanks. Along this distance you trace distinctly the road used for ox carts to pass between the tanks, and you can distinctly see at several points the old ruts of the wheels and the tracks of the oxen. The floor of the cave was then moist and muddy—now it is very dry and hard. You pass through the Dome, and reaching a large mass of rock, called, from its shape, "The Giant's Coffin," you leave the main route and pass for a mile or more through a long avenue, where there are some large

Stalactites and Columns.

In one of the latter, called the "Arm Chair," you can have a short rest, if desired, before going on to "Lover's Leap" and other noted features. The ceiling of this avenue, being rather low, is filled with the names of visitors, the earliest dates being in 1816, only a few years after the cave was discovered. These names were made by placing the candles, then used by guides and visitors, on poles, and holding them near enough to the ceiling to trace the letters with soot from the flame. One is struck with the fact that among the thousands of names found recorded there, you see none belonging to persons who ever became distinguished. Is not this almost invariably the case with those whose chief ambition seems to be to leave their names in places of public resort?

Passing Lover's Leap you descend gradually into a narrow and most dismal chasm, and visit a number of interesting objects. Among these is the celebrated "Bottomless Pit," a very deep cavity, of which you can just manage to see the bottom from the light of a burning taper dropped into it. The taper used by the guide to give a brighter light in such places is very simple. It consists of wide strips of coarse brown paper about a foot long, folded till about an inch in width, and saturated with oil. They make a sufficiently good light.

"Goblin's Dome,"

Examined by aid of these tapers, is one of the most impressive sights there. It is a very high and deep fissure, some 50 feet wide, into which you look through a small window-like opening in the main avenue. Being of about the same size all the way, it is supposed to be at least 150 feet from the point of observation to the bottom, and quite the same distance to the top. But when one comes to recall the peculiar and impressive features of this wonderful "hole in the ground," nothing looms up more vividly in tender recollection than "Fat Man's Misery" and the "Corkscrew." Through both of these your correspondent "worked his passage." How narrow! how tortuous! how low! what a squeeze it was! It was close, warm work. Once will do, Mr. Editor, I never knew before that any such places existed in Mammoth Cave. So let me caution any of our fleshy friends, e. g., A., of Santa Barbara, or E. C., of Temescal, if ever they visit the cave, to find out where those narrow defiles are, and let them alone. If they venture in, it might prove the death of them. If one of them got fastened there the guide could never get him out again in the world. I saw how it was myself. None of us would want to find a tomb already hewn out in these catacombs of nature. It requires no small amount of dodging, squeezing and crawling to get through "Fat Man's Misery," and the "Corkscrew" alive.

In a beautiful dome called

"Star Chamber,"

Because when the lights are partially hidden behind a huge rock, myriads of stars seem to glisten in the dark arched roof, the guide is in the habit of removing the lights entirely by taking them through a side avenue leading from one end of the chamber to the other. He does this that you may realize the intensity of darkness

which reigns supreme in man's absence.

Oh! darkness and solitude most profound!

DeQuincy says there is no solitude equal to that of being alone in a large city. Such solitude is great indeed; but pardon me, if inclined to think, from experience, that the profound loneliness felt when by one's self in Mammoth Cave without a light, far surpasses DeQuincy's picture of solitude. Being lost in the cave for a short time has been known to craze people. Who can wonder at it?

Before reaching "Star Chamber," you find in the main avenue two

Small Stone Houses,

The only remaining ones of eight erected there in 1842 to receive consumptive patients, according to a queer idea of some physician who thought the dry air of the cave would benefit them. For three weary months, shut out from healthful light, 12 consumptives lived there with four nurses, until one of the patients died. Suddenly that mode of treatment became unpopular, and the survivors left.

Passing the river Styx on its natural bridge, and visiting Lethe, we found the water and boats in such condition that it was deemed best not to try to reach Echo river. Indeed, just a week before the back water from Green river had been 20 feet deep over much of the muddy, treacherous path by which we reached this modern

"Stream of Oblivion."

So, having made a circuit of some five miles or more, we rapidly retraced our steps, and it was really a relief to escape from such oppressive gloom, and to enjoy once more the bright light and exhilarating air of a glorious winter's day. Certainly Mammoth Cave well deserves its reputation as one of the world's wonders. To examine it richly repays those who have the opportunity to do so. J. W. A. WRIGHT.

Steamer Suevia, January, 1876.

Tin.

Tin ore in America? Yes! In Maine a large deposit exists. At a meeting of the Boston Society of Natural History, December, 1860, Professor C. H. Hitchcock, State Geologist of Maine, exhibited specimen crystals weighing over five pounds. Gen. Samuel J. Anderson and Hon. E. L. Hamlin, of Portland, Maine, have similar crystals. David W. Hendrickson, of Red Bank, N. J., Professors Holmes and Billings, of McGill College, Montreal, Professor Forrest Shepherd, of New Haven, and Professor Averill, of Cambridge, Mass., have many crystals of Tin ore, or Cassiterite, from the Maine mine. In 1867, John W. Quincy, Esq., of New York, one of the most prominent metal merchants, made an effort to have this valuable ore brought into use, but prominent parties interested in the monopoly of the Tin trade have persistently discouraged the development of these Tin mines. Prof. Goodale asserts that no where in the known world have so large specimens been found as in this locality in America. The above authority we consider sufficient to pledge our belief that the centennial, which promises so much for the use of our Iron abroad, will equally encourage the use of our Tin at home. Tin is one of our largest articles of commerce and of import; its uses are numerous and vast, and the consumption very great indeed. Europe has drawn many millions annually from us in gold in payment for Tin. Why not turn the golden balance of trade in our favor, through such channels of traffic as recognize the stamp and credit of the United States Government as a legal tender? Our mines are richer, our ores purer, and more easily produced than those of Mexico and Europe. Our people should feel a national pride in any new discovery, and assist it as a part of the means to give a balance of trade in our favor, and so far aid in stopping the disgrace which our national credit has sustained in the prolonged depreciation of our currency.—[New York Mercantile Journal.]

It ought to be also well known that valuable deposits of tin are found in the Temescal Mountains some 60 or 70 miles inland from Los Angeles, in this State. These mines would have been actively worked long ere this, had it not been for the unsettled nature of the title to the land on which they are located; but we believe this matter is now in a fair way of adjustment, and that we may reasonably expect soon to add tin among the valuable articles of export from California.

A NEW WINE.—The ravages of the phylloxera among the vines of France have incited many attempts to discover a new kind of beverage to take the place of the juice of the grape. The Marquis de Villeneuve reports that in China a pseudo-wine called Tsien-lai is much used, which is concocted from a preparation of iron plants, common in that country, and mixed together in certain proportions. The plants are dried and powdered and made into a paste, which is sold in the form of balls and squares, at the rate of about three pence a pound. One square or ball will make several pounds of fermented liquor, pleasant to the taste and much resembling wine, which is now sought after by Europeans and others living in China. A fictitious brandy is also prepared in the same way, and the manufacture is so simple that with a capital of £5 or £10, to purchase the apparatus, a man may make 25 gallons of "brandy" a day. The Marquis de Villeneuve affirms that the liquors thus produced are of good quality and possess no injurious ingredients.

THE EXPORT OF AMERICAN LEATHER has more than doubled within three years. The export of 1873 was 800,000 sides; that of 1875 was 1,800,000.

The Mines of Arizona.

Col. H. C. Hodge furnishes some interesting information to the *Santa Barbara Index* in regard to the mines about Mineral Park, Arizona. We condense from his letter of March 18th as follows:

For a month past I have been exploring the wonderful mineral veins for a distance of 30 miles about Mineral Park, and find much of interest to the general public, and of especial interest to those interested in mines and mining. My explorations have been in the Cerbat, Hualapai and Peacock mountains. In the Cerbat range is included the Mineral Park, Chloride, Cerbat and Stockton mines, which extend in a northerly and southerly course some 15 miles, with a width of two to five miles. The number of claims located and recorded in these localities run well up into the hundreds, if not thousands. The ore from the Keystone, which is now being worked to a depth of 200 feet, is now paying at the Mineral Park mill \$200 per ton. Much of the selected ore from this mine will go far above these figures. The ore now on the dump pile of the Lone Star is very rich in horn and ruby silver. It is believed that the ore now at this mine now ready for milling will average \$300 per ton. The ore of the Index is nearly as good. The Metallic Accident, T. J. Christie owner, has shipped some 15 or 20 tons to San Francisco, which gave over \$1,400 per ton. At Chloride camp, five miles north, there are a large number of equally good mines as those mentioned, and the owners of several of them have shipped many tons of the ore to San Francisco, which paid from \$300 to nearly \$1,000 per ton. The most promising of the Chloride mines are the Empire, Schenectady, Pink Eye, Pennsylvania, etc. The mines at Mineral Park and Chloride are all silver, carrying more or less galena, antimony, sulphurets, etc. At Stockton there are some very fine developments, and from time to time shipments of ore to a large amount have been made to San Francisco, which gave returns of from \$200 to \$1,000 per ton.

The great want of the country is railroad communication, and capital to erect mills and machinery to work the rich ores. The Mineral Park mill company, incorporated in California, have a new and complete five-stamp mill now in operation, and is a decided success. Since starting a few days since, it has been working ores from the Keystone mine of this place, and from the Hackberry mine, 30 miles east in the Peacock mountains, the average yield being \$200 per ton; this result in any other country would create a wonderful excitement. The Hualapai mountains are about 25 miles east of south of this place, and extend far off to the south for nearly 100 miles. The range is a mineral belt of great richness.

The Peacock mountains are some thirty miles east of Mineral Park, and in this mountain is the celebrated Hackberry mine, discovered about one year since by Messrs. Ride-mour & Crozier, who are now working it successfully. Messrs. Davis & Randall, merchants of this place, have just completed a five-stamp mill for working the ore, which will average over \$200 per ton. A score or more of small but perfect five and ten stamp mills are needed in this country, and would be a source of great profit to the owners, who, for a time, could have \$40 and \$50 per ton for working ores, and would help to launch this country upon a sea of prosperity never excelled in any mining country. The water in all this mountain region, with few exceptions, is very good, though not as abundant as in the mountains of California. Grass is abundant in all the mountain regions, as well as upon the great plains and valleys, but in most of the great plains and valleys water is scarce. In time, no doubt, artesian water will be found in abundant quantities, as the geological and other indications give assurance as positive as can be found in any country.

The African Coast.

The surf on the African coast, says a letter writer, is ever a wonder and a danger. There is no coast in any part of the world which possesses less ports or harbors of refuge. You may travel a thousand miles almost without finding a cove or harbor where a ship could anchor quietly without being rocked by the surf waves. Try along the whole of the grain, the ivory, the gold and the slave coasts and there is not one port. But, fortunately for ships trading to those places, there is seldom a hurricane blowing, so that they are able to anchor about a mile from the shore. There is never any dead calm, though the sea in the morning is stirred up into wavelets by the breeze from oceanward. During the night it is moved by the land breeze, so that ships anchoring in the roadsteads are ever to be seen rolling uneasily; they are never at rest. Unceasingly the long lines of waves are to be traced rolling onward to the shore, gathering strength as they advance nearer, until, receiving the ebbing waters flowing from the beach from preceding seas, there is a simultaneous coiling and rolling, and at once the long line of waves is precipitated with a furious roar on the land. Where the water meets a rock a tall tower of spray and foam is suddenly reared, the wave line is broken and is in mad confusion. Where the beach is smooth and of sand you may trace a straight, unbroken line of foam nearly a mile long.

THE BLOOD COST OF COAL.—It is estimated that within the last half century 50,000 men have been killed by accidents in the coal mines of England, and 200,000 severely wounded.

MECHANICAL PROGRESS.

Some English Metal Work for the Centennial.

The London Times, of the 11th ult., contained a description of a handsome collection of artistic metal work which has been prepared by Messrs. Elkington & Co. as their contribution to the Centennial exhibition. It consists of several hundred articles, worth, in the aggregate, about £100,000, and will be put in a place of honor in the center of the English department, where it will occupy a quarter of the space beneath the lower. The collection does not include any of the more common kinds of electro-plating, such as spoons, forks, dishes, or other articles of daily use, but consists entirely of work of a highly decorative kind in dinner services, vases, shields, mirror frames, plaques and tazza. The whole may be arranged under the three principal classes of *repousse* work in silver, enriched by gilding and enamellog; *repousse* work in iron, decorated by inlaid and damascened patterns in gold and silver; and champlevé and cloisonné enamels. In all of these departments considerable progress has been made since the Vienna exhibition; but in none of them is it more noticeable than in the cloisonné enamel, which far surpasses the Chinese or the modern Japanese examples of the art, and even approach very nearly to the old Japanese. After an interesting description of the process of enameling at Birmingham, the Times goes on to say that among the noticeable specimens of the Messrs. Elkington's cloisonné, may be mentioned a pair of cylindrical vases, about a foot high and four or five inches in diameter, covered with floral decorations of great beauty. One of the finest specimens of the *repousse* work in iron of this firm is an oval mirror frame damascened with birds and arabesques. The arabesques are simply burnished, but the birds are sculptured until the outline of almost every feather may be traced. Other fine specimens will be sent to the exhibition, among them a dessert service, a tazza, and some plates. The dessert service consists of five pieces in iron *repousse*, inlaid with gold and silver, relieved by exquisitely chased panels of oxidized silver, and supported on crystal pillars, delicately engraved with incised and gilt ornamentation. The tazza is in *repousse* silver, with a border of iron, damascened and incised with gold, and the principal subject is a Pompeian lady at the toilet, attended by her slaves. The design was executed by M. Morel-Ladenil, the artist of the Helicon vase and of the Miltonshield, who was engaged two years upon it.

The decorative dinner and dessert services are of various styles, Egyptian, Grecian, Pompeian, Romano-Greek and Renaissance. They are made either in massive silver or in copper electro-plated, in either case relieved by gilding; and two complete services, consisting of center pieces, plateaux, candelabra and fruit stands, are richly decorated with champlevé enameling and paneled with gold.

There is also a selection of reproductions of the art metal works in South Kensington museum, and not the least excellent part of the collection will be the show cases of shonized wood richly adorned with incised and gilt decorations. The designs of the greater part of the work were prepared by M. Willms, chief artist for the Messrs. Elkington.

TWENTY-TWO INCH PLATE.—The thickest armor plate ever produced was rolled at the works of Charles Cammell & Co., limited, at Sheffield, recently. From four and one-half inches, the size has been increased step by step till it has reached 14 inches, and Messrs. Cammell & Co. have succeeded in producing one of 22 inches, this being eight inches thicker than any armor plate ever yet rolled. The plates of which this is a sample are intended for the *Dandolo* and *Duilio*, two war vessels now being built in Italy for the Italian Government. The gun to be used in testing this great plate, which weighs 35 tons, is one of the 100 ton guns now being made by Sir William Armstrong & Co., at Newcastle. The vessels are to have two turrets, and each turret will contain two of these enormous pieces of artillery. Mr. Cammell stated that if these guns succeeded in penetrating this plate he should have no hesitation in rolling one of 30 or even 40 inches in thickness. — *Monetary Gazette*.

IMMENSE WIRE ROPES.—Commodore Shufeldt has ordered the proper authorities of the Boston navy yard to make several five-inch steel wire hawsers. These will probably be the largest wire ropes ever made. The Navy Department has use for immense hawsers to tow monitors and vessels in distress. They are put on board the men-of-war for use when required. The usual appliance is a 12-inch hemp rope, but it swells when wet, and gets very heavy by absorption of water. The steel wire hawsers will be seven inches less in diameter, much lighter, non-absorbent, more pliable and durable, and in every respect better. This is a curious and, in fact, wonderful advance in the application of steel and iron to commercial uses. A hemp hawser, 12 inches thick, is a wonderful thing in itself, but a steel wire hawser, five inches in thickness, better answering the same purpose, is something fruitful of thought to the student in shipbuilding and rigging. — *New York Bulletin*.

Patents in the United States.

The last annual report of the U. S. Commissioner of Patents states that there were received during 1875, 21,638 applications for patents, of which 14,837 (including reissues and designs) were granted. Following the practice of former years, the commissioner gives a table showing the number of patents granted to residents of the different States, Territories and foreign countries during the year. It is interesting to notice the wide differences which exist. For instance, in Idaho Territory only one patent was granted, the population being 14,999. Against this we may put the State of New York, where 3,771 patents were issued, being in the proportion of one patent per 1,163 inhabitants.

The density of the patent taking population is greatest of all in the District of Columbia, where one person out of every 615 appears to be a patentee. This, however, can hardly represent the inventive activity of the district, and the high proportion is probably due to the fact that many inventors acquire a temporary domicile in Washington for the purpose of prosecuting their applications. The absolute number of patents taken out is small, reaching only 214. New Mexico Territory contributes the smallest proportion of patents, there being only one to every 37,101 inhabitants. The agricultural States do not, as might have been expected, make much show. Only 31 patents (one to every 32,161) come from Alabama. North Carolina contributes 37, or one to every 28,956, and South Carolina sends 46, or one to every 17,513 persons.

The office is rapidly outgrowing the accommodation which the building affords, especially in the model rooms. About 10,000 rejected models were removed in consequence "to an open space under the roof of the west wing of the Patent Office building. The floor of this attic and the model shelves are composed of rough boards, and the place itself is very difficult of access. The trouble increases yearly, and if no provision can be made for relief in this regard it will be necessary to do away entirely with models." The sooner the better, say all who have anything to do with patents. — *Iron Age*.

The Telemeter.

A Berlin correspondent of the London Times states that, according to trustworthy information, M. Le Boulanger, a Belgian major of artillery, has succeeded in constructing an instrument indicating the distance between two armies by the mere report of the discharge. The moment the enemy fires a shot, the action of the report upon the telemeter—that is the name of the machine—marks the distance to a fraction. The instrument is entirely self-acting, easily kept in order, and requires no particular experience of intricate calculations to use it aright. The experiments to which it has been subjected in the artillery grounds of this and some other countries are stated to have been a complete success, as regards cannon. Whether the machine works with the same accuracy the report of one or many rifles, and whether the small specimens for infantry and cavalry use are as reliable as the larger ones attached to the guns, is not quite so certain. While the artillery trial may be regarded as at an end, experiments in the rifle grounds are still going on, and, it is said, with fair prospect of producing a satisfactory result. Should the latter expectation be realized, war will have a very different thing from what it has been, seeing that in the last campaign only one shot in ten hit; but even if the invention is confined to the artillery, its effect must be tremendous considering the present deadly efficiency of fire arms. One of its principal advantages, it is supposed, will be to enable the gunners in a coast battery to determine the position of a hostile ship—a calculation hitherto fraught with special difficulty. The adoption of the telemeter by the German artillery on land and sea may be regarded as certain.

Cork Springs.

We are assured by reports of recent experiments that cork is likely to supersede the use of India rubber in machinery, especially where the pressure is very great. A pressure of great power will destroy India rubber, causing it to break or split up into small pieces, losing its elasticity entirely. No such result follows in the case of cork, properly prepared. Cork is first soaked in a mixture of water and molasses, which gives it some softness and permanent moisture. It is then cut into discs eight inches in diameter. As many of these as are needed are put into a cast-iron box, an iron lid applied, and corks being down to half their original thickness, a bolt is run through the center and nut and screws hold them in place. A spring thus formed, tested by a ten tons pressure, shows an elasticity like compressed air.

GIFFARD'S COLD AIR ENGINE.—The principle of the cold air generators is well known. When air is subjected to compression, heat is developed. When deprived of the heat, and subsequently allowed to expand, it re-absorbs heat so eagerly as to produce a notable lowering of the temperature, which is susceptible of application to a variety of practical purposes. A new description of airtight cylinder, new joints, and a new stuffing box have enabled Mr. Giffard to so far improve upon previous machines that his cold engine, when driven by an ordinary steam engine, will make 20 pounds of ice for each pound of fuel burned.

SCIENTIFIC PROGRESS.

Measuring Earthquakes.

There is scarcely any movement or change in nature which modern science does not measure. No matter how great or how small the phenomena may be, some instrument is devised for gauging and registering them. The vocabulary of science fairly bristles with strange polysyllabic names ending in *meter*, which have been formed as designations of these ingenious contrivances. Meteorology has its thermometers and barometers, and scores of less familiar hygrometers, pluviometers, anemometers, and so on; and every other branch of physical science can show a similar catalogue.

The *seismometer* is a measuring machine of which some of our readers may never have heard. The word is derived from the Greek *seismos*, a shaking, and means an earthquake measurer; for the physicist applies his gauges even to earthquakes. There is an instrument, known as the *sphigmograph*, by which the heart is made to record in expressive curves the force, rapidity, and other characteristics of its beating. The *seismometer* measures the heart-throbs of Mother Earth, and registers every pulsation that thrills her mighty frame. Of course it is only in certain localities that this can be done, just as it is only to certain parts of the body that the *sphigmograph* can be applied. One of these localities is the observatory on Mt. Vesuvius, of which Professor Palmieri is the director. This observatory is situated on a spur of the mountain, close to the Hermitage or half-way house on the route usually taken by ascending tourists. The seismometers are in the second story of the building, but rest upon solid piers of stone reaching to the earth. The instrument for the automatic registration of vertical shocks is a fine metallic point, suspended by a coil of wire just over the surface of a cup of mercury. The slightest upward motion of the earth carries the mercury up to the wire, completing a galvanic circuit which instantly stops a clock and rings a bell to notify the observer to reset the apparatus and observe future phenomena. To measure the intensity of vertical shocks, small magnets are suspended over a cup of iron filings by means of coils of wire of different strengths. When a vertical shock occurs, some of these magnets dip into the iron filings, and to one of them a light index is attached for measuring the intensity of the shock. For horizontal shocks the registering apparatus consists of U-shaped glass tubes, partially filled with mercury, and set to the four cardinal points. A small weight rests on the mercury and is attached to a silk fiber, which runs over an ivory pulley and has a counterpoise at the other end. On each pulley there is an index and circular scale to mark the angle through which it turns. A horizontal shock causes the mercury to rise in the tube or tubes corresponding to the direction from which it comes, the weight is raised and the pulley marks, by means of the index, the angle through which it has turned. At the same time the mercury in rising completes a galvanic circuit which stops a clock and rings a bell. The galvanic current from either registering apparatus also starts another clock, the pendulum of which has hitherto been held out of perpendicular, and this clock allows a roll of paper to be unwound, on which, by means of electricity, a pencil traces the movement of future shocks, the spaces between the markings indicating the time elapsing between the shocks.

Professor Palmieri, who has the charge of these seismometers and all the other apparatus of the observatory, is not only an eminent physicist, but a brave man. He has remained at his post when Vesuvius was in active eruption, calmly watching the indications of his instruments, amid the elemental warfare, cool as a veteran under fire, though like him really in peril of his life and fully conscious of the danger. We trust that it may not be his fate to fall a victim to his devotion to science, as the elder Pliny did in an eruption of the same Vesuvius 18 centuries ago. — *Jour. of Chemistry*.

NITRO-GLYCERINE TRANSPORTATION.—Senator Jones, of Nevada, has introduced a bill in the United States Senate, which absolutely prohibits the transportation from one State or Territory to another, or to or from a foreign country, of nitro-glycerine in any other form than that of dynamite, and prohibits the transportation of the latter substance except by merely freight conveyances, and on condition that it is packed in metallic cases, and unaccompanied with any means of exploding it. In the event of a death being caused by explosion when dynamite is transported in any other manner, every person who knowingly permitted or aided its transportation is to be deemed guilty of manslaughter.

PRESERVING PLANTS WITH THEIR COLORS.—A French gentleman, M. Boulade, has discovered that if freshly gathered plants are spread out between sheets of filtering paper in the usual herbarium manner, and then heated between two bricks in an oven for two or three hours at about 150 degrees Fahrenheit, they will be perfectly and permanently preserved without impairment of the most delicate colors. The process is rendered more rapid and certain if the layer of filtering paper next the flowers be changed after about an hour.

Fascinations of Science—Straightening the Mississippi.

The Mississippi river between Cairo and New Orleans was 1,215 miles long 176 years ago. It was 1,180 after the cut-off of 1722. It was 1,040 after the American Bend cut-off (some 16 or 17 years ago). It has lost 67 miles since. Consequently, its length is only 973 miles at present. Now, if I wanted to be one of those ponderous scientific people, and "let on" to prove what had occurred in the remote past by what had occurred in a given time in the recent past, or what will occur in the far future by what has occurred in late years, what an opportunity is here! Geology never had such a chance, nor such exact data to argue from! No "development of species," either! Glacial epochs are great things, but they are vague—vague. Please observe: In the space of 176 years the Lower Mississippi has shortened itself 242 miles. That is an average of a trifle over one mile and a third per year. Therefore, any calm person, who is not blind or idiotic, can see that in the old Chlotio Silurian period, just 1,000,000 years ago next November, the Lower Mississippi river was upwards of 1,300,000 miles long, and snaked out over the Gulf of Mexico like a fishing-rod. And by the same token any person can see that 742 years from now the Lower Mississippi will be only a mile and three-quarters long, and Cairo and New Orleans will have joined their streets together, and be plodding comfortably along under a single mayor and a mutual board of aldermen. There is something fascinating about science. One gets such wholesale returns of conjecture out of such a trifling investment of fact. — *Mark Twain*.

New Specific Gravity Apparatus.

M. Paquet announces to the *American Chemist* the arrangement of a new specific gravity apparatus, which is particularly useful in experiments on small quantities of solids and in mineral determinations. The instrument has the form of Baume's areometer, with a pear shaped bulb, carrying a stem, which is surmounted by a larger tube closed at the bottom and divided into cubic centimeters and tenths of cubic centimeters. The 0 is placed on a level with the second cubic centimeter, and the instrument is ballasted in such a way that it sinks into the water to the lower end of the stem when the tube is filled with water to the 0 of the large tube, containing, for example, 2 c. c. of the liquid. The stem has also a graduation, of which the 0 is at the lower end, and the other divisions are obtained in the following manner: Suppose the instrument is to be used for weights below 6 grammes; into the upper tube, containing already water to 0, is poured 6 grammes or 6 c. c. of water. It sinks to a certain depth, which is marked 60, and the distance between that point and 0 is divided into 60 parts. To use this instrument, put into the large tube 2 c. c. of water; it rises just to 0. Plunge it into water, it stops at 0. Put the body into the upper tube, which will bring the level of the liquid in this tube to the division 3, for example. The volume of the body is then 3 cubic centimeters, while the instrument sinks into the water to a certain division of the stem, 55, perhaps. The weight added is 5.5 grammes; the density is then 5.5—3.

This instrument can be used for determination of the specific gravity of liquids, in which case the operation is very nearly the same as with Roussau's apparatus.

A QUATRAIN OF GOOD RULES FOR THE STUDENT.—The following four precepts of D-scarles are quoted by Viollet-le-Duc in his "Discours." The first is never to admit the truth of anything without thorough conviction; that is, sedulously to avoid precipitation or prepossession of judgment, and to accept nothing as fact which does not recommend itself as clearly and distinctly to my mind that there can be no possible occasion for doubt. The second is to divide the subject I am investigating into as many heads as it is capable of, to the end that its difficulties may be the more readily resolved. The third, so to order my thoughts that, beginning with the most simple and comprehensible objects, I may gradually ascend to the contemplation and understanding of the most complex, assuming a regular order of induction in those subjects which do not seem naturally so to arrange themselves. The last, always to make such thorough and comprehensive reviews of my studies as to prevent the possibility of omitting or not giving due weight to any of the considerations which bear upon them.

NEW ELECTRIC LIGHT.—A new electric light, experimented upon some weeks ago on the roof of the Siemens-Halske works, at Berlin, proved so successful that ordinary writing could be read at the distance of a mile. When the light was thrown toward the clouds by means of a mirror a luminous train appeared thereon, which much resembled the tail of a comet, and drew together great crowds of spectators in the streets. Signals made by the instrument were also repeated upon the clouds, becoming thus visible at a very great distance. The experiments were made in the presence of a large number of artillery and other branches of the government service, and were continued for nearly two hours. The instrument, which is provided with a locomotive engine, will be set up in the Tegel artillery polygon for further experiment, the German war department having the intention of purchasing several of the machines for military use, both afloat and ashore. — *Revue Militaire d'Etranger*.

Mining Share Market.

The week opened upon a rather weak market, with the share decidedly in the ascendant, and almost all the stocks showed a decrease in amount of sales and prices realized from our latest last week's quotations. On Tuesday there was quite a tumble, notably among the Bonanza stocks, Ophir going down to \$64½ and Con. Virginia touching \$75½, the lowest figure it has reached since the division of the stock. Wednesday morning witnessed a rally, and an advance all along the line of from \$5 down; but the upward tendency had spent its power before the day was over, and to-day (Thursday) opened upon another declining market, with lower quotations for some of the leading stocks than they had attained on Tuesday. It is evident that the bears have not, as yet, ended their attack on the leading Bonanza stocks, as the up-and-down movement manifested in these securities within the past few days indicates a mighty struggle of powers behind the scenes.

Consolidated Imperial made its first appearance upon the boards on Monday, meeting with good demand and selling at \$7. It has since been fluctuating between that figure and \$6.

CENTENNIAL TRAVEL.—It is stated that every berth on every foreign steamer to arrive in Philadelphia from the 15th of May to the 15th of September has been taken. Passengers intending to go to Philadelphia from this coast over the Central Pacific are also engaging sleeping arrangements for several weeks and even months ahead. A large portion of the accommodations for the month of May are already secured by parties who have booked their names for certain days on which they wish to start.

OPPOSITION OF ENGLISH MINERS TO INNOVATIONS.—It is well known that the English miner, as a body, are very jealous of innovations. The miners of Cornwall have ever been adverse to the introduction of machinery, as, to their minds, being calculated to supplant manual labor. Gradually, however, it has been introduced in several mines, and we are glad to learn that the miners are now disposed to regard with favor the very machinery which comes nearest to hand work. In Cornwall, at present, the boring machine question is much discussed by mine managers, agents and workmen. The working miners now seem to realize that instead of taking the bread from them these machines are calculated to alleviate their labor and to obviate much physical toil; they are saved all the hard work entailed by hand boring and drilling. In addition to this, the machine does four times as much work as a man. A great deal—perhaps too much—was expected from the Darlington drill at Wheal Arger. At Dolcoath, a boring machine called the "Barrow," is about being introduced. The principal feature of this horer is, that instead of allowing it to be automatic, man has been made an integral part of its labors. At all events, prejudice against the best achievement of scientific skill is on the wane in Cornwall.

THE NEW POSTAL TREATY.—Postmaster Coey received an official letter from the Department Thursday morning, conveying the principal terms of the new postal treaty between the United States and Japan, to take effect immediately. The postage on letters hereafter will be five cents a half ounce and for each fractional half ounce. Papers will be charged two cents each under four ounces and on all other packages two cents for every two ounces. Pre-payment in all cases compulsory, and all letters or other packages not prepaid will be sent to the Dead Letter Office. The treaty takes effect immediately.

MINING SUMMARY.

The following is a mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

Good Pay.—Amador Ledger, April 15: Richd. Stocken, who now goes by the nickname of "Lucky Dick," is still turning over the auriferous earth in the neighborhood of his quartz claim, four miles above Volcano. Himself and another man are sluicing, and have averaged about \$15 each per day. There are also three small but very rich quartz veins, from which rock is being extracted. Stocken is entitled to the "lucky" prefix. He has scooped out of the earth and into his pocket over \$1,000 in a few weeks from the placer deposits alone, and the crushing of his quartz will realize probably as much more.

LINCOLN MINE.—The Lincoln company has let a contract to run a drift eastward, for \$5.75 per foot. Some claims, we believe, have secured the contract. The object is to prospect for the main ledge, as it is thought, notwithstanding the large bodies of ore heretofore met with, the mother lode has not been reached.

BUTTE.

GOLD.—Oroville Mercury, April 14: Messrs. Gummert & Brown are now the owners of the Gummert quartz ledge, situated in Oregon gulch, some six miles from town. The ledge has been worked at times since 1850. That is, the mill started then and run for three years and eight months, and was shut down at the time it was having lost everything. Some eight years ago it was started up again and is now running. Mr. Gummert was in town last Saturday, and left at the banking house of Riddout, Smith & Co. three small shares, valued at \$2,750, as the result of 12 days' run of 11 hours per day. They have a five-stamp mill, which runs by water, and the edge varies in width from six to eight feet. The quartz also varies much in value. It runs from \$8 to \$30 per ton. The mill is some two miles distant from the ledge. The tunnel has been run in such a crooked manner that it is impossible to work to advantage, and a new one will be run soon. The owners feel confident that they have reached a depth that will give them a constant return of good quartz.

CALAVERAS.

GLENCOE CONSOLIDATED.—Calaveras Chronicle, April 16: There is no more promising mining property in the county than that of the Glencoe Consolidated company. The ledge is a wide one, clearly defined, and all of its strata carry gold. A correspondent, writing us with reference to the Consolidated ledge, gives the following interesting particulars: "Parties struck a heavy body of ore on the first north extension of the Glencoe Consolidated. Ore prospects well. Still further north Eldred has a splendid prospect on the same vein. Two thousand feet south of the southern limit of Glencoe Consolidated the same vein is being opened with favorable indications, a shaft eight feet in depth showing two feet in width of ore, which will easily mill \$20 per ton. Still further south the vein has been traced and located as far as Esperanza creek. This remarkable fissure is now located for three miles in linear extent, cropping heavy bodies of pay ore, worth not less than \$20 per ton, at short distances throughout the entire length." The late discovery made by Messrs. Lewis & Fairchild is on the Glencoe Consolidated ledge. We understand that the company intend commencing active operations upon an extensive scale shortly.

RICA ROCK.—Rock of unsurpassed richness has lately been discovered in the Grasshopper mine at Mosquito. By means of the new machinery lately put up the shaft has been cleared of water and the south level extended a short distance. The mine has always borne the reputation of containing the richest ore in the country, but nothing equalling the rock now being extracted has ever been previously discovered. The quartz prospects, by the ordinary method, at least \$2,000 per ton. Parties who have seen the rock inform us that it is absolutely the richest they ever saw. The work of cutting out the rich ore will be pushed as rapidly as possible.

SHEEP RANCH.—Calaveras Citizen, April 16: We saw on Wednesday a piece of quartz from the Ferguson & Wallace mine, Sheep Ranch, which was extremely rich in gold. The piece was about two by one and a half inches square, and contained one ounce of the precious metal. A ton of such rock is estimated to be worth \$20,000. The Ferguson & Wallace is the only mine working at present. The shaft is down 240 feet, and levels are being run. Mr. Trump is putting in the pump, and the mill is kept steadily running on good ore. Mr. Woods, also, has his mill running on good ore. Rumor says he has sold his mine for \$10,000. The Calaveras company's mine, superintended by Messrs. Nicowander and True, is working 20 stamps.

EL DORADO.

NEW TUNNEL.—El Dorado Republican, Apr. 13: A preliminary survey is being made by the E. W. & D. G. M. company for the purpose of running a tunnel from the falls in Big Canon, through Spanish hill to Texas hill, for an outlet to the rich gravel mines owned by said company. If this tunnel is run it will go through some of the richest gravel in the State, and the county, and many rich leads will undoubtedly be struck. The most practical miners speak favorably of the enterprise. A good starting place has already been developed at the True lode. From the mouth of the tunnel of this mine, the hill rises very rapidly, so that if the tunnel were commenced there, it would soon run at a depth of 600 feet. The tunnel is now run to the hill 60 feet, all the way on good milling ore. The ledge or lead is six feet wide, with good walls and a gouge of 14 inches. The prospects are very flattering. The location could not be bettered. The superior advantage in this canon for mill sites are most inviting, and the water power advantages cannot be excelled. 15 or 16 inches of water, with the fall or pressure that can be had here of 600 feet, would run a 20-stamp quartz mill.

NEVADA.

BLUE TENT.—Nevada Transcript, April 11: The ground owned by the Blue Tent mining and water company is situated at Blue Tent, about five miles from this city, and consists of about 600 acres. The gravel is a part of the rich lead and gravel river channel on which the mines at Columbia hill are situated, and the channel has also been traced to the extensive claims of Jacobs & Sargent, at Quaker hill. The gravel of the lead at the point worked in the mine at Blue Tent is 400 feet in depth, and has proved by numerous clean-ups the past winter to be of a very remunerative character. The principal reason for the tunnel is, that it is known that the South Yuba claim, in which a tunnel is run from the hillside below, a distance of 600 feet, and which is 100 feet below the bedrock in that claim. This tunnel will furnish an outlet for the tillings for more than five years' work. The hole being washed out through the gravel has not yet got down to the bedrock, and much more has been done so far than what has been of surface dirt, because it keeps caving down, yet it has all paid over 30 cents for each inch of water used. The mine has the best dumpage of any in this section—it being 750 feet from the mouth of the tunnel to the bed of the South Yuba river below. Two nozzles are run on the South Yuba, one on the Blue Tent and two on the Enterprise ground. The water at present used is obtained from several ditches owned by

the company, and they purchase 800 inches of water from the South Yuba canal company. They also own a ditch which is 30 miles in length, and cost for construction \$100,000. It was commenced by Tozer, the former superintendent, in 1874, but he only completed about 800 rods that season, besides some work on a tunnel. Under the present management the work was again commenced in May, 1875, and was completed in October. There were 750 Chinamen employed on the works all last summer, and 250 white men. The ditch takes the water of the South Yuba river at a point about 200 vertical feet below the point where the South Yuba canal company gets its supply, and about the same height above where the Omega water and mining company obtains its supply. There are four and one-half miles of solid fluming at the head of the ditch, and a tunnel just below it of 1,000 feet in length. The ditch around the steep hillside, where there is danger of snow slides, was blasted into rocks most of the way, so that during the past winter not a break has thus far been made. This method was more expensive, but it will prove most economical in the end. At one of these points 450 rods of the ditch cost \$38,000 for construction. The ditch will carry 5,000 inches of water as far as Omega, where it is expected 1,000 inches or more will be sold. The ditch, when the dam is necessary, will be run to the mines of the company. During the present season it is the intention of the company to erect extensive dams above the head of the ditch at different points wherever there is an uncultivated water shed, so as to secure an abundant supply of water for the entire season. The snow on the upper line around the ditch is from eight to twelve feet in depth. Men are at work cleaning it out, and will get water to running in the course of two or three weeks. The company have expended, exclusive of purchase money, over \$250,000 for permanent improvements, and have not done yet, though it is expected the proceeds of the mines will pay for what will be done hereafter.

PLACER.

MINING ITEMS.—Dutch Flat Forum, April 13: The three claims which have commenced within the last few weeks to open to the bedrock, namely the Badger, Franklin and Silver Star, are piling up working away. The three claims are now being cleaned up, and are cleaning up for the first time this season. All the other claims we believe are under full headway, washing away the gravel as fast as water aided by labor and power can do it. At Gold Run, the Cedar and Indiana Hill claims having finished cleaning up and rigging up, are again washing. The Miami, Darlett and Gold claims are washing the latter, however, only at odd spells, much time being devoted to working up a deep ground sluice, in order to reach the gravel bank. The ditches are all running to their full capacity, and our miners continue to wear smiling countenances.

SAN BERNARDINO.

IVANPAH MINES.—San Bernardino Times, April 8: The sale of the McFarlane brothers' Ivanpah mines—machinery, teams, etc.—has been consummated to a New York company, for the sum of \$200,000. The money, although not paid here yet, was placed in the Bank of California, and tendered to the security of the company, who have been in San Francisco, and are likely to run the mines on a considerable larger scale than heretofore. It is rumored that it is the intention of the McFarlane Bros. to commence operations immediately on other mines in the district, equally rich with the old mine.

SOME representatives of capital are going in a week's time to Ivanpah to visit the copper mines of that place, which are very rich, the ore running as high as 60 per cent.

THE Big Blue mining company start upon the 15th of this month in Lone Valley district, on their property there. Mr. I. F. McFee, as superintendent, intends to sink another 100 feet on the shaft, now down 135 feet.

MR. R. D. BROWN, of Hot Springs district, is expected back in a few weeks to complete negotiations with an English company for the sale of the Consolidated Balance company mines, of that place.

LUCKY BARNEY LEE, of Lee district, is reported as having bought into the late discoveries made by the indefatigable Joe Voshay. The mines are situated about 20 miles from Palm station, near Whitewater. The assays in the gold are very high, and a defined ledge is reported.

TRINITY.

MONSTER SLIDE.—Weaverville Journal, April 15: Last week a slide in the Union Hill claim filled up the claim to a great extent and carried one of the giants down a shaft. The slide then appears to have been only a foretaste of what was to follow. About four acres, actual measurement, has broken away and is advancing steadily and bodily down over the bedrock worked in former years. All the shafts through which the company worked have been closed. The slide settled forward about 40 feet on Wednesday, completely closing up the shaft. The bank is broken far back of the ditch and the houses, which will probably slide in also. The company will clean up their ditches and bedrock ditch, which are thought to contain several thousand dollars. A partial clean-up, made some time since to put in new blocks, yielded about \$2,000, showing that the claim has pay dirt of extraordinary richness. The slide has probably shut off gravel washing for the season, which is much to be regretted, as the company have been cutting and tunneling bedrock for the past two years and had only opened in the gravel last fall, with very flattering prospects.

Nevada.

WASHOE DISTRICT.

OPHIR.—Gold Hill News, April 13: Daily yield, 150 tons of ore, keeping three mills steadily running. There is little or no change in the looks of the ore but the quality of the ore is being steadily improved. The 100-ft level a drift is being driven southward along the ledge, preparatory to cross-cutting at some future date. On the 1600-ft level drifts are being run along side of the ore body, both north and south, which, so far as exposed, is showing well. The east shaft, extending from the 1455-ft level down to the 1703-ft level, has been cleaned up until the top of the last set of the station. Members of the 1700-ft level has been reached. There is yet, undoubtedly, a large accumulation of water, slum and debris on that level which will have to be removed before the prospecting drifts can be resumed. The new incline machinery was given another trial a few days since, and found to work as perfectly as it was possible for it to do. The fourth compartment of the shaft is nearly completed down to the 1465-ft level.

JUSTICE.—Sinking the shaft below the 1000-ft level is again going rapidly ahead, the bottom in fair working ground. The north and south drifts at the 1000-ft level are steadily advancing and will soon have a considerable extension of the ledge. The main south drift has been cleaned out and repaired in nearly to the face. As soon as the face is reached it will be pushed ahead to cut the ledge and connect with the south winze now being sunk below the 600-ft level. That winze has now reached within about 10 feet of the 800-ft level. A sufficient amount of ore is being extracted from the 600-ft level to keep the Spring Valley mill steadily crushing.

LADY WASHINGTON.—Sinking the shaft is going steadily forward at a very fair rate of speed. The last 15 feet sunk has penetrated a fine clay wall, and the bottom is just now entering quartz of a highly encouraging character. The clay wall and quartz has a regular dip to the south and east about 15 degrees, and judging from the character of the formation the shaft has every appearance of being on the point of striking the

fame ledge found in the Justice mine. The large pit or the pump hoh at the 500-ft station is about completed.

GOULD & CURRY.—The shaft is again in excellent working condition, and the repairs to the north drift on the 1700-ft level are fast approaching completion. The excavations for the new pumping machinery are being pushed vigorously forward. The putting in of this machinery will not interfere at all with the working of the lower levels of the mine, as it is being placed entirely separate from them.

UNION CO.—The face of the north drift on the 1300-ft level is still in quartz and low grade ore of a very encouraging description. The body of quartz is gradually widening out as the drift advances northward. The bottom of the winze being sunk below the 1300-ft level, near the south line, is still in quartz and low grade ore. The opening out and widening of the quartz bodies on this level is giving almost a certainty of the development of paying bodies of ore when the ledge is reached on the 1455-ft level.

BALTIMORE AND AMERICAN FLAT.—The east cross-cut on the 1050-ft level is steadily advancing, without any change of interest. The north and south drifts from this cross-cut are both making fair speed and are each just entering quartz of a much more compact and richer character than that which has been found in that portion of the mine. Sinking the incline is making good headway. It has nearly reached the 1250-ft level.

NORTH CON. VIRGINIA.—Sinking the shaft is being pushed with great force and energy, the bottom in porphyry and black quartz of a very encouraging character. This quartz is of the same porous nature, and is filled with base metal sulphurets. The flow of water shows no great increase. The shaft is now down 830 feet. The machinery is working well, and everything moving along with the utmost smoothness.

MEXICAN.—There is no change in any portion of the mine. The northeast drift on the 1455-ft level is still advancing parallel with the ore vein, laying bare as it progresses a considerable portion of the ledge, ready for cross-cutting whenever it is desirable to do so. The spots and streaks of quartz occasionally encountered in the course of the drift are of the most encouraging description.

CON. VIRGINIA.—Daily yield 500 tons of ore, keeping the mills all running and crushing up to their full working capacities. The ore breasts show no change, and the immense chambers of rich deposits seem but a little reduced by the amount of ore extracted. The east drift on the 1600-ft level, running to connect with the C. & O. shaft, is steadily advancing, the face in good running ground. Great caution is taken to keep the diamond drills a long distance ahead of the face, so as to guard against tapping the heavy body of water now being drained by the C. & O. shaft. The flow of water at the bottom of the C. & O. shaft is very strong for the past week, reaching at one time as high as 53 inches, miners' measurement. It is now reduced to 43 inches. The pumps handle it with the most perfect ease, but so large a flow makes the work of sinking necessarily very slow. The shaft has been sunk 15 during the past week, the bottom being in excellent working ground and were it not for the flow of water.

CALIFORNIA.—Daily yield 300 tons of ore. Widening out and opening the ore breasts is gradually progressing on the 1500-ft level, the ore being of a very rich quality. By the last of the month the breasts will be sufficiently opened to admit of extracting a sufficient amount of ore to start another mill crushing. Sinking the winze below the level of cross-cut No. 6 on the 1550-ft level is going steadily ahead. With the exception of the extraction of ore, sinking this winze is about all the work that is being done in the mine at present. This winze will be continued downward to a depth of 200 feet or more for the double purpose of prospecting the ore vein and affording an air winze whenever the development of the mine below the 1550-ft level is commenced.

DAYTON.—The flow of water struck in the shaft last week is still strong, and has been a great hindrance to let it drain itself well before commencing the sinking. The water tapped is the same as that on the 500-ft level, that having disappeared as soon as the flow in the shaft commenced. Tapping the water at that point drains the ledge down to the 750-ft level, and leaves a perpendicular section of the ledge 350 feet in depth ready for cross-cut and prospect. On the 500-ft level the north and south drifts are steadily advancing, following the east side of the ore vein. These drifts have now laid bare the ledge for a distance north and south of 600 feet. This will give room for some lively work when the cross-cutting of the ledge is commenced. It is the intention to soon open another station at 750-ft level. The south drift on the 300-ft level is making the usual good progress.

DILLON.—Drift on the 2000-ft level is steadily advancing toward the ledge, the face is well grained, hard, black dyke, with a strong re-embance to a slate, with occasional spots of crystallization mixed through it. There is a slight seepage of water in the face, which appears to be steadily on the increase. It certainly cannot now be long before the ledge will be reached at that point, as this body of dyke has never been found over 40 feet in thickness on the levels above. Sinking the main incline is making steady progress, the bottom in fair working ground. Sinking the north winze on the 1400-ft level, to connect with the upraise from the 1700-ft level is also making rapid headway. The upraise from the 1700-ft level, to connect with this winze, is making steady progress.

HALE & NORCROSS.—The site of the old works on the surface presents a happy aspect. In one hand large forces of men are employed excavating deep pits and laying the immense stone foundations for the new pumping machinery, while on the other carpenters and stone masons are preparing the materials, and teamsters delivering the timbers and rough stone and heavy timbers. The preparation for the erecting of pumping machinery is going on the Gould & Curry, Savage, and Hale & Norcross, who are taken in connection with the immense pumps of the Chollar Combination and the C. & O. shaft, will be sufficient to extract a perfect river of water, when once in full operation, and it taken together, when completed, will have cost \$2,000,000—or more.

SIERRA NEVADA.—Sinking the shaft is going steadily forward, without stoppage or delay. It is now down 1,735 feet. The east prospecting drift on the 1000-ft level is steadily advancing in very favorable ground. The ore vein on this level is 30 to 90 feet in width, 60 feet of which is solid quartz, of a very fine character. The north and south drifts on the 1500-ft level are both steadily pushed ahead, the face of the north drift showing good indications of ore. There are no changes to relate of the prospecting drifts on the 1250-ft level. The main south drift on the 1000-ft level running to connect with the bottom of the winze now being sunk below the level of the north drift on the 700-ft level of the old shaft, is being pushed ahead with all possible energy.

BEST & BELCHER.—The main connecting drift on the 1700-ft level with the Gould & Curry, is again nearly completed, in good running order. As soon as everything is in good condition the prospecting of the ore vein on this level will again be commenced, and if no heavy flow of water is encountered to the contrary, the full character of the vein determined. It will probably take some two weeks yet to put everything in working order and to get ready.

YELLOW JACKET.—Owing to the necessity of putting in new T rails in the main incline shaft, all work on the 1940-ft level has been stopped for the present, except driving the north and south drifts from the middle cross-cut. Both these drifts are making good progress, and each are in very favorable looking ground. The east cross-cut on the Conifer line, on the 1740-ft level, is in 80 feet, the face in porphyry mixed with quartz.

CHOLLAR-POTOSI.—Daily yield 65 tons of ore, the assay value of which is \$35 per ton; this ore being taken

entirely from the old upper workings. The prospecting drifts on the 1250-ft levels have all been stopped for the present. The east and west cross-cuts from the main south drift on the 1300-ft level are steadily advancing, without any valuable change to report. Sinking the Combination shaft is making splendid progress.

SAVAGE.—The deep excavations for the reception of the heavy stone foundations and bed sills for the powerful pumping machinery now in course of construction at San Francisco are being pushed ahead with all possible energy. The tank stations and hot pits in the shaft are nearly completed down to the 1800-ft level; otherwise, no change to chronicle.

JULIA.—Sinking the main shaft is going steadily ahead, the bottom in excellent working ground. The south cross-cut from the main southwest drift on the 1600-ft level is steadily advancing, the face in very favorable ledge matter. The face of the main drift shows but little change. No material changes to report of the prospecting operations on the 1400-ft level.

UTAH.—The shaft has reached the 750-ft level, at which point a station is being opened for the purpose of cross-cutting and prospecting the ore vein. The flow of water is that point is still strong, and the rock tough and hard. There is nothing new to report whatever to report of the workings on the old upper levels.

KOSKUTH.—The north and south drifts on the 500-ft level are steadily advancing, laying bare the east side of the ledge, ready for cross-cutting whenever the management shall so decide, and the water is sufficiently drained. The face of the main south drift on the 350-ft level is still in quartz rich in gold.

KNICKERBOCKER.—Sinking the shaft is going steadily ahead, the bottom in fair working ground. It will not now be long before the shaft will have reached a depth sufficient at which to open a new level. The flow of water remains about the same as for some time past. It is easily handled by the pump.

SILVER HILL.—The main east drift at the fourth station level shows no change during the week. The water has disappeared from the north winze near the Justice line, and is undoubtedly drained by the flow struck in the main incline a week ago. The water in the incline remains about the same.

OVERMAN.—Sinking the main shaft is going steadily forward, the bottom still in hard blasting rock. The flow of water is still quite strong. The east cross-cut, on the 1100-ft level, is steadily advancing without any valuable changes to note. Nothing now of any other portion of the mine.

IMPERIAL.—The main north drift, on the 2000-ft level, which was stopped during the greater part of last week, is being again steadily advanced, the face still in rich ore. No changes of interest in any other portion of the mine. The prospects of the mine are daily improving.

GLOBE CONSOLIDATED.—The hoisting machinery, and in fact everything in connection with the surface works, has just been given a good overhauling and put in the best possible condition for a good summer's work. Work will be resumed in the mine in a very few days.

BELOHER.—Daily yield, 600 tons of ore. The mills are all running steadily, crushing up to their full working capacity. There is little or no change in any portion of the mine. The erection of the new pumping machinery is being forwarded with all the dispatch possible.

TROJAN.—The new buildings are completed and the machinery is being placed in position as fast as the workmen can succeed in doing it. It will not now be long before the hoisting works will be in fine condition for operating the mine, and the extraction of ore commenced.

CROWN POINT.—The south drift from the east cross-cut on the 1700-ft level is steadily advancing, the face in quartz and low grade ore. There are no changes to relate to report of any of the prospecting operations on the 1600-ft level.

COOCH.—Work is progressing as usual on the 550-ft level, with no important changes to note. Sinking the shaft is somewhat impeded by the strong and steady flow of water at the bottom.

CONSOLIDATED COCK.—This location is a consolidation of seven claims, of 1,500 feet each, situated north and east of the Utah. A shaft has been sunk to the depth of 210 feet, cutting a vein of promising looking ore. In the northwest drift on the 200-ft level, the rock is 75 feet in width, and has been opened upon, showing to be about seven feet in width, of fair grade and very promising appearance.

SILVER CITY.—The ore breasts and stopes continue their excellent yield of ore, with plenty in sight to keep the mill running steadily for months to come. The first shipment of bullion was made to San Francisco a few days since, but we did not learn the amount.

ROCK ISLAND.—The prospecting drifts on both the 650 and 850-ft levels are steadily advancing, the ledge showing large and well defined, but as yet affording no pay ore of any considerable extent.

CALEDONIA.—Sinking the shaft is making the usual fair progress, the rock in the bottom still being quite hard and the flow of water strong. Everything in and about the mine is working well.

COSMOPOLITAN.—All work is confined to the upraise at the north end, which is now 42 feet above the tunnel level, following the inclination of the ledge and showing some good milling ore.

SOUTH COSMOTOK.—Drifting ahead with the main west cross-cut proceeds well, the water being completely drained. Face of drift in fair working rock, showing streaks of low grade ore.

VICTA.—Drift south on main track level in very promising ground and making good headway. The old levels are yielding the usual quantity of pay ore.

MOANING STAR.—Sinking the shaft is being pushed ahead with all possible vigor, the bottom in good blasting ground. Good headway is being made.

VALLEY.—Sinking the main incline shaft is making splendid headway, the bottom in soft ledge material, carrying streaks of rich ore.

DANEX.—The water is being steadily drained from the shaft, and at the present rate of progress the 400-ft station will be clear in a very few days.

FLORIDA.—New machinery all completed and ready to start up. Sinking deeper will be started forthwith, as soon as the water is pumped out.

LEVITIAN.—Drift on the splendid ledge matter, most of which is low-grade ore, with rich streaks and bunches.

PIOTOU.—Still drifting north, with streaks of quartz coming in, giving good assays. Not ready to cross-cut yet.

NORTH DAYTON.—Fine stringers of quartz, giving good assays, continue to be met with in the face of the drift.

BOSTON.—Sinking the shaft is making the usual good progress, the bottom in very favorable material.

SENATOR.—The water is nearly drained to the bottom of the shaft, ready to resume sinking.

NORTH CARSON.—Placing the new machinery and getting ready for the active development of the mine.

PROSPECT.—Shaft sinking at a very good rate of progress, and everything working well.

DANIEL.—Sinking the shaft is making the usual good progress, the bottom in the 140-ft level pushing ahead in fine ore indications.

BALTIMORE CONSOLIDATED.—Face of drift from the lower level of the Nevada still hard rock.

NEVADA.—Face of north drift at lower level still showing finely.

PHIL SHERIDAN.—The new works are fast approaching completion.

MONUMENTAL.—Sinking this shaft is going steadily forward.

SUPERIOR.—Shaft and drift progressing and showing finely.

ROUCH AND READY.—Shaft sinking lively as usual. Nothing new.

A New Source of Rubber.

The coast region about Congo, in Africa, is becoming quite an important source of caoutchouc. The material from this locality is derived from a gigantic creeping vine (*landolphia*), which grows principally along the water courses. It covers the highest trees, and frequently considerable extents of forests are festooned down to the ground, from tree to tree, in all directions with its thick stems, like great hawsers. Sometimes its stem is as thick as a man's thigh. Above, the trees are nearly hidden with its large glossy leaves of dark green hue, and studded with beautiful bunches of pure white star-like flowers, most sweetly scented. Its fruit is of the size of a large orange, yellow when ripe, and perfectly round, with a hard brittle shell; inside it is full of a soft reddish pulp of an agreeable acid flavor, much liked by the natives. It is not easy to obtain ripe seeds, as the creeper is a favorite resort of a villainous, semi-transparent, long-legged red ant—with a stinging bite, like the prick of a red hot needle—which is very fond of the pulp and the seeds distributed through it.

Every part of the creeper yields a milky juice when wounded; but, unlike the juice of the American rubber tree, this milky sap will not run into a vessel placed to receive it. It dries so quickly that a ridge is soon formed over a cut, and the flow arrested. When collecting it, the natives make long cuts in the bark with a knife, and as the sap gushes out they wipe it off continuously with their fingers and smear it on their arms, shoulders, and breasts, until a thick covering is formed. Then they peel it off and cut it into small squares for transportation.

A NEW FUEL—ANTHRACITE COKE.—Much interest is being created in regard to a new kind of furnace fuel, which has recently been introduced in England, and which is known as "anthracite coke." It has been made near Swansea, England, from a mixture of 60 per cent anthracite, 35 per cent bituminous coal, and five per cent pitch. This coke is said to be exceedingly bright, small in grain, moderately sonorous, and of average density. It is remarkably clean. It is claimed that 192 pounds of this coke melted 30 owt. of pig iron and old railway chairs. The iron came down very hot and clean, although the quantity of coke used was less than half that usually employed at the same works. The Landore steel works company have two furnaces in blast, one on hematite, the other on spiegelisen. The latter has only recently been started; the first has been going some time on anthracite coke. The furnace is 65 feet high and 17 feet in the bosh. The make of pig iron is 300 tons per week, each ton requiring two tons of 50 per cent ore, and 18 owt. of coke; with the best Glamorgan coke 27 owt. were required to do the same work. The facts are very remarkable, and indicate that the new fuel possesses unusual value.

AN OLD ANVIL.—Mr. Norman Seymour, secretary of the Livingston county (N. Y.) historical society, writes to the *Courant* as follows: Among the relics that have been brought out so far this Centennial year, I have found in our town an old anvil weighing from 80 to 100 pounds, marked on it in figures out in the iron, "1632." This anvil was brought over from England about the year 1632 by John Moses, who settled in Dorchester, near Boston. In 1667 he moved to Simsbury, Hartford county, Conn. He had a son Timothy, and Timothy second had a son Elisha, and Elisha second came into the Genesee valley, New York, at an early day and brought the anvil with him. He died at Mount Morris in 1847, aged 86 years. This rare curiosity of the olden time is now in possession of the family of the late Elisha Moses, but it should have a place in your cabinet of Puritan relics, the Athenaeum.

DIVING IN THE OCEAN FOR FRESH WATER.—One of the hottest regions of the earth is along the Persian gulf, where little or no rain falls. At Bahrein the arid shore has no fresh water; yet a comparatively numerous population contrives to exist there, thanks to copious springs which burst forth from the bottom of the sea. The fresh water is got by diving. The diver, sitting in his boat, winds a great goatskin bag around his left arm, the hand grasping its mouth; then he takes in his right hand a heavy stone, to which is attached a strong line, and thus equipped he plunges in and quickly reaches the bottom. Instantly opening the bag over the strong jet of fresh water, he springs up in the ascending current, at the same time closing the bag, and is helped aboard. The stone is then hauled up, and the diver, after taking breath, plunges again. The source of these copious submarine springs is thought to be in the green hills of Oman, some 500 or 600 miles distant.

A RICH PLACER MINE.—The Spring Valley company, from Cherokee, brought down on April 8th a bar of gold valued at \$22,000. This is the third lot brought down inside of three weeks. The first lot was \$12,000, the second \$61,000, and now comes the third lot of \$22,000, making a total of \$95,000. There is yet a large part of the flume to be cleaned up, the result of which we will probably give in our next.

THE mucilage used by the government for postage stamps is composed of dextrin two ounces, acetic acid one ounce, water five ounces, alcohol one ounce.

Rapid Increase of Narrow Gauge Railroads.

Very few general readers, we opine, have any adequate idea of the extent which the narrow gauge railroad question is assuming in the United States. The following facts in this direction, confined exclusively to the single State of Ohio, will be read with interest. They have been carefully compiled by the *American Manufacturer*, from which journal we condense:

Dayton and Southeastern, 105 miles. Contract given out and work commenced at \$6,500 per mile.

Springfield, Jackson and Pomeroy, 121 miles. Contract given; to be ready for 15 miles and iron by May 1st, 1876, at \$11,400 per mile.

Wheeling and Lake Erie; graded part way for a standard gauge, but changed to narrow because they could not raise money to build the standard. The road, equipped and finished for a large business, \$13,000 per mile. Road 199 miles long.

Wheeling, Alliance and Lake Erie; part graded; will be over 100 miles in length.

Toledo, Meumee and Grand Rapids; 23½ miles long, 7½ miles finished and running on it. The 7½ miles cost equipped, with rolling stock, about \$8,000 per mile. It was not expected this road would pay for several years, but it paid big from the very first, and now no one can buy the stock at any price reasonable.

The Toledo and Ohio; a short road running from Minerva, Ohio, to Carrollton, and is to be extended.

Toledo and Ann Arbor; 70 miles long; graded for a standard gauge; now being finished for a narrow gauge.

Beilaire and Southwest; grading is now going on; length over 100 miles.

Cleveland, Collamer and Lake View is now standard gauge; going to change to narrow gauge; acknowledge their mistake and say they are out over \$25,000 cash by using "dummies" and not making it narrow gauge at first. Road is 7½ miles long.

The Miami Valley narrow gauge will be 120 miles long; now being surveyed.

Cincinnati and Westward narrow gauge; iron partly laid and locomotive running; 4½ miles long.

College Hill narrow gauge; iron partly laid; locomotive running.

Smithfield and Rush Run narrow gauge is just starting; will be 8 miles long.

Lebanon and Cincinnati narrow gauge is just starting; length about 20 miles.

Toledo and Petersburg narrow gauge; 20 miles long; nearly ready for iron.

J. M. Cook, Toledo, Ohio, has a project about completed to build a narrow gauge from South Haven, Mich., to Toledo, via Paw Paw and Ottawa, Mich. Will be 40 or 50 miles in Ohio.

These are all in Ohio, or partly so, and together over 800 miles of narrow gauge is now being built.

The average cost of Ohio standard gauge roads, now running, is over \$60,000 per mile, while you can build narrow gauge roads for one-fourth that amount, completely equipped, and can haul ton for ton of paying load at the same rate of speed and 15 per cent. less cost of operating.

The above facts present a significant intimation of the rapidity with which this new method of cheapening travel and transportation is rising in public favor, recommended as it is by a relative cost, compared with the standard gauge, so low as to bring its lines within the reach of every well settled neighborhood in the country.

Acetylene Copper.

The explosive character of acetylene copper is well known. Many serious accidents have occurred from its presence—spontaneously formed—on copper pipes employed for conveying illuminating gas. Such accidents have resulted from slight blows with a hammer or some other iron tool given by workmen when engaged in making repairs, etc. Such accidents have become so frequent of late, and are so violent, dangerous and unexpected in their occurrence, that a more general knowledge of this dangerous explosive should obtain, among workmen and others, who, from their calling, are exposed to its danger.

The knowledge of the explosive character of this compound has recently led to the preparation of a similar compound, for practical use in filling percussion caps, torpedoes, etc.

The mode of producing this new compound or salts of copper is as follows: To a solution of sulphate of copper is added enough hyposulphite of soda, in solution, entirely to destroy the blue color. To another portion of the blue vitriol solution, ammonia is added, until the blue precipitate, at first formed, dissolves to a dark blue solution. The two solutions are now mixed; and after long standing a violet colored salt crystallizes out of the beautiful blue liquor. It is this salt which becomes explosive when mixed with chlorate of potash. The composition of the "violet colored salt," above referred to, and which constitutes the new explosive, is not given by the authority quoted; neither is any reference made to the probable cause of its explosive nature. It may possibly be due to the nitrogen imparted to it by the ammonia.

AMERICAN HARDWARE IN ENGLAND.—The *Ironmonger* for February says an American merchant is in Sheffield with a consignment of light steel hay forks, shovels, spades, etc., of an American make, and he is offering them at quotations much under Sheffield prices for similar goods. Such goods of American make have long had a market in England.

USEFUL INFORMATION.

How to Use Leather Belting.

A practical correspondent writes to the *Scientific American* some suggestions concerning the use of leather belting: Leather belts should be thoroughly oiled before using. A good way to apply the oil, where there is much belting to be oiled, is to have the belting run off from one reel to another, through a pot of oil, with suitable rubbers to wipe off the superabundance of oil. Another good method of applying the oil—and perhaps it would be preferable in a majority of cases—is to put it on with a paint brush. This should be done on both sides, with no sparing hand. A belt thus oiled will not require a second application under ten years, unless there be much dust to absorb the oil, and then it may be put on very sparingly compared with the first application. The advantages that an oiled belt has over a dry one are these: 1. It lasts longer. 2. It requires less power to drive the machinery. 3. It may be run much more sleek, which makes the bearings less liable to heat, requiring less oil and less attention.

There are but few people who pay any attention as to how they put on a cross belt, consequently they are just as likely to get it on wrong as right. There are but two ways to put such belts on. The right way is this: Put the belt on in such a manner that the drive pulley will have a tendency to rough up the splices; then when the splices come to the crossing they will smooth each other down instead of catching under each other's corners and tearing open a splice.

A quarter twist belt should never be used where it can be avoided; but when it is used, it should be as narrow as practicable, and the pulleys should be large. Increasing the width of a quarter twist belt does not increase its power in the same ratio as in a straight or cross belt. There is not more than one per cent. advantage in using an oiled belt with the grain side next to the pulley, which will hardly compensate for the ugly look which a belt presents when put on in that manner.

In lacing a belt, the lacing should never be crossed on either side. To lace a belt in this manner, there must be one more hole in one end than the other, consequently there will be a hole in the middle of one end, which is the place of beginning. Draw the lacing to its middle through this hole, lace each way to the edge and back to the middle again, and you have by far the nicest joint that can be put into a belt. No one will ever lace the old way after once getting "the hang" of this method.

BLACK VARNISH FOR IRON.—A durable black and shining varnish for iron is made by adding to oil of turpentine strong sulphuric acid, drop by drop, stirring until a sirupy precipitate is formed, and no more of it is produced on further addition of a drop of acid. The liquid is now repeatedly washed with water, until the water exhibits no more acid reaction. The precipitate is next brought upon a cloth filter, and after all the water has run off, the sirupy mass is fit for use. This is painted over the iron with a brush, being previously diluted with oil of turpentine, in case it does not flow well. Immediately afterward, the paint is burnt in by a gentle heat, and, after cooling, the black surface is rubbed with a piece of woollen stuff dipped in linseed oil. This varnish is said to combine chemically with the metal, and does not wear or peel off.

TO MAKE PUTTY.—Pulverize the required quantity of whiting, which has been specially dried, and pass through a sieve of 45 holes to the square inch; mix the powder with as much raw linseed oil as will form it into a stiff paste, which should be well kneaded and left for a day or so; it must then be worked up, a small quantity at a time, so that it may be rendered quite smooth, and that balls of the dry whiting powder may not be imprisoned in different parts of the putty, for these would make their appearance when the putty was being used, and would, of course, injure the adhesiveness of the composition. Putty should be kept in an earthenware pan covered with a wet cloth. Putty which has become hardened may be made again fit for use by warming and beating it up, and kneading it whilst in that condition.

STRAIGHTENING AND BENDING PIPES.—In order to straighten lead pipe, if the bore of the pipe is one inch or more in diameter, dress out a wooden rod small enough to enter a hole the size of the bore; then point one end, grease the surface thoroughly, and work and drive the rod into the pipe. Draw the rod back and turn it a trifle at every blow. If the pipe is small, less than one inch in diameter, drive in a pointed iron rod, turning it at every blow, so that the rod may not stick so tightly that it cannot be withdrawn. To bend a lead pipe without forming kinks, fill the bore with dry sand. To bend an iron pipe, fill the bore with dry sand, stop the end with stiff clay, heat the pipe where it is desirable to have the curve, and the pipe will bend readily without making kinks. If the dry sand will not run out, water will wash it out.

A SIMPLE BROWN DYE for cloth is made of japonica, half a pound; bichromate of potash, two ounces; alum, one ounce, and water, five gallons. Put the ingredients in a vessel, dissolve, immerse the goods, previously wet with warm water, and simmer for three hours.

Fraud in Graham Flour.

Because Graham flour is recommended as a very healthy article of food, it should not be assumed that all Graham flour is equally good or even nutritious. The fact is Graham flour is rapidly coming to be as much an article of suspicion as ground coffee or spices or any other of the thousand and one adulterations that are daily practiced. The commonest form in which Graham flour is seen is that made from a medium or poor class wheat, and while not properly adulterated, it may be justly characterized as swindling of the meanest kind, for the reason that the product is largely used by dyspeptics and others in imperfect health. The miller who palms off on his customers Graham flour made from anything save the choicest of wheat is one of the meanest of all villains, and if he is not aware of it should be told so. Graham flour properly made is nearly as costly an article as bolted flour ground from the same wheat, and, therefore, when you are offered Graham at much less than the best bolted flour you are being victimized; it is either adulterated or it is made from inferior wheat. A common form of adulteration, and one that is practiced by at least one retail flour dealer in this city, is to take a barrel of flour costing about five dollars, add to it about 60 pounds of bran, 25 pounds middlings, and the same quantity of corn meal. The result of the mixture is 306 pounds of stuff costing about \$6.45, or a fraction over two cents a pound; while Graham flour made from the best wheat cannot be sold now at less than three and a half to four cents a pound. And yet this vile stuff is being swallowed by people in search of better health, when they would do about as well on a diet of hot white biscuit. There is a fortune in store for the miller here in St. Louis who will make a strictly pure article of Graham flour from the best winter wheat, from which the outer husk of the bran shall have been removed before grinding. That man will establish a good reputation, make money, and confer a blessing upon thousands of his fellows. —*St. Louis Trade Journal.*

HARDENED PAPER.—Recent French journals speak of a method of rendering paper extremely hard and tenacious, by subjecting the pulp to the action of chloride of zinc. After it has been treated with the chloride it is submitted to a strong pressure, thereafter becoming as hard as wood and as tough as leather. The hardness varies according to the strength of the metallic solution. The material thus produced can be easily colored. It may be employed in covering floors with advantage, and may be made to replace leather in the manufacture of coarse shoes, and is a good material for whip handles, the mounting of saws, hammers, combs, and other articles of various descriptions. An excellent use for it is in large sheets for roofing. Paper already manufactured acquires the same consistency when plunged, unsized, in a solution of chloride.

ALCOHOL AS A FOOD PRESERVER.—A Swiss professor of chemistry has patented a new process for the preservation of meat, fish, vegetables, butter and cream, the novelty of which consists in the addition of alcohol to the usual solution of salt. The only probable objection to the method is the hardening of the fiber of the meat. One advantage would be the combining of meat and drink, as is done by the London water companies, and the mixture might suit weak-backed teetotallers. For preserving butter, the professor mixes 2 lbs. alcohol of 90 degs. strength, with every 100 lbs. of dairy produce.

A SIMPLE way of cutting glass is to crack it with a very fine, needle-like gas flame. Start the crack with a file, and then apply the flame, which may be produced through a minute perforation in a glass connected with some rubber piping so as to allow of the flame being conveniently carried from point to point. The crack will run before the flame in any desired direction.

Wax flowers, if left out in the drizzling rain, will be thoroughly cleaned in a short time.

GOOD HEALTH.

Candy.

So much has been written about the relations of candy to health, and particularly to diseased teeth, that it would seem presumptuous to add even a word. But supposing the question cannot be settled at once, there are some facts about candy, or sugar rather, which I have not seen mentioned. As a food, it is a failure. The chemist tells that cane sugar contains three elements. The human body has some fourteen elements. How can three elements make fourteen? Dogs fed on sugar died in 40 days. Their eyes ulcerated and came out. Dogs fed on nothing lived just as long. The system has a natural loathing for food containing nothing but sugar. We pass then to the occasional use of sugar. Does it affect the condition of the organs of the body? Several years ago Dr. S. Weir Mitchell, of Philadelphia, proved that he could produce cataract of both eyes in half an hour, by simply injecting a teaspoonful of a saturated solution of sugar beneath the skin of a frog or Guinea pig. Dr. B.

W. Richardson, of Loudon, has confirmed this, and these results are received by the medical profession as satisfactory. Now if a teaspoonful of sugar solution will make a frog or Guinea pig totally blind in half an hour, can sugar be regarded as an innocent substance for young and growing persons, especially when they diet so largely upon white flour, which is chiefly composed of starch, whose chemical formula is identical with that of sugar? According to Dr. C. B. Agnew, of New York, out of 1,000 children under 18 years of age, in a large school in his vicinity, 703 were found with defective organs of vision when examined with the ophthalmoscope. Have we a right to infer that sugar and starch diet have anything to do with this large percentage of deficient eyes? The experiments quoted show that sugar does act promptly, quickly, and terribly upon the substance of the crystalline lens of lower animals. Can we deny the probability of its action upon the eyes of human beings? Mark, we do not say it does thus act. We simply raise the question. We wish the State board of health would have it investigated, as it is a matter germane to their invaluable department of labor.

Now for candy and diseased teeth. Lime and phosphorus form the chief mineral ingredients of teeth. The organic matter (i. e. that like sugar) amounts roughly to about 20 per cent. of the whole tooth. The mineral matter and water make the remaining 80 per cent. In other words, sugar gives the teeth, under the most favorable construction, 20 per cent. of its food only, when it is used as an aliment. But sugar cannot be used as an exclusive aliment, as death would ensue. Used occasionally when the other food has its normal amount of mineral ingredients, candy, when pure, probably does not harm the teeth. But used frequently, in connection with flour diet, there is no doubt that it will promote the decay of teeth. When organized substances are fed, they must receive all the elements that enter into their composition. Failing to receive these, their vitality is impaired and decay results. Teeth fed with candy do not receive any mineral elements. No phosphorus and no lime are found in candy, but they constitute the main part of teeth. Hence we see that candy and teeth are not interchangeable things, and that candy-eaters must not be surprised if their teeth fail. —*Journal of Chemistry.*

Dangers of the Shop.

We give in what follows an abstract of an instructive lecture lately delivered before the Society of Arts, by Dr. B. W. Richardson, on "Industrial Pathology; or, the Influence of certain Injurious Occupations on Health and Life." There are, said the lecturer, seven active causes producing disease amongst the working classes—first, noxious inhalation of dust and gases; second, exposure to soluble chemical substances; third, mechanical impact of foreign bodies; fourth, physical injuries from unnatural postures, etc.; fifth, exposure to damp or impure air; sixth, contact with organic parasitic forms; and seventh, excess of muscular work, etc. Turning his attention in the first instance to the injury caused by the inhalation of various sorts of dust, Dr. Richardson alluded to the growth of oidium on the vine, which growth was checked by the blowing of sulphur dust on the plant. Oidium was described as a white parasitic fungus, which appeared not only on the vine, but also in the throats of persons suffering from diphtheria. Ammonia often proved injurious to haters. The vapor of turpentine produced a specific form of disease, and was more injurious to house painters than the lead to which their peculiar complaints were commonly attributed. Sulphide of carbon was useful as an anæsthetic agent, but produced disease and insanity when inhaled for any time by men who used it in their occupations. The fumes of nitric acid affected farmers deleteriously. The vapor of chlorine affected bleachers injuriously at first, but on continued use became innocuous. Aniline produced two distinct forms of disease—one neuralgia, the other ulceration, and when the inhalation resulted in death, the flesh was found to be of an aniline or mauve color. Nitro-benzene vapor produced headache, and the vapors of metals caused various diseases of the lungs, brain and stomach.

The remainder of the lecture went to show that apoplexy, paralysis, insanity and various other serious diseases, were producible in artisans by contact with injurious substances and vapors, especially that of lead, which affected not only the workman using it, but his offspring. Cleanliness and care, the speaker affirmed, would greatly mitigate this mischief, but still the startling fact remains, that among those workmen who were exposed to the vapors of lead, the deaths were 38 per cent. in excess of ordinary mortality. Dr. Richardson had no radical remedies to suggest for the majority of his illustrations, and contradictory as it may appear, it is unfortunately true, that it would have made no sensible difference had he done so, on the principle possibly that familiarity with danger breeds indifference to, or contempt of it, experience has demonstrated that, as a class, no reforms are more difficult to introduce than remedial measures of this character.

PERFECT SLEEP.—The sleep of perfect rest is dreamless—a kind of sleep not produced by laudanum, chloral or any other drug. Remember this, young people, at the beginning of your lives. Do healthy work enough to weary you, and you will sleep a healthy sleep, and be doubly sure of a good old age.

DOMESTIC ECONOMY.

How Vienna Bread is Made.

Prof. Horsford was one of the United States scientific commission to Vienna at the world's fair of 1873. He has made a report concerning the famous Vienna bread, which has been issued from the Government printing office. He describes the Viennese bread as follows: "It is a smooth, irregularly rounded small wheaten loaf, of uniform weight. It presents a rich reddish brown crust and a delicately shaded yellow, almost white, interior. It is always light, evenly porous, free from acidity in taste or aroma, faintly sweet, without the addition of saccharine matter to the flour or dough, slightly and pleasantly fragrant, palatable without butter or any form of condiment and never cloying upon the appetite." Good fresh middlings flour, Prof. Horsford says, would compare favorably with the average Hungarian flour used in Vienna. The next requirement is fresh pressed yeast. This is already made in the United States. It is not difficult to manufacture, since it is made by skimming the froth from beer mash in active fermentation.

Next follows the very important operation of mixing. Into the middle of a zinc-lined trough, about two and a half feet wide and eight feet long, semicylindrical in form, the Vienna baker empties his flour sacks. Then into a pail holding about five gallons, equal parts of milk and water are poured and left to stand until the mixture attains the temperature of the room, between 70 and 80 degs. Fah. It is then poured into one end of the trough and mixed with the bare hand, with a small portion of the flour to form a thin emulsion. The press yeast is next crumbled finely in the hands and added in the proportion of three and a half ounces to every three quarts of liquid, and then one ounce of salt in same proportion is diffused through the mixture. The trough is now covered and left undisturbed for three-quarters of an hour. Then follows the incorporation of the flour from the neighboring heap; and as this is the last of the ingredients we may write the recipe as a whole, thus: Flour, eight pounds; milk and water, three quarts; pressed yeast, three and a half ounces; salt, one ounce.

The mess of dough, being left quiet for two hours and a half, becomes a smooth, tenacious, puffed mass, of yellowish color, which yields to indentation without rupture and is elastic. It is now weighed into pound masses, and each lump is then cut by machinery into 12 small pieces, each of three-quarters of an inch in thickness. Of each one of these the corners are brought together in the center and pinched to secure them. The lump is reversed and placed on a long dough board for further fermentation, until the whole batch is ready for the oven. Before being introduced into the latter the rolls are again reversed and restored to their original position, having considerably increased in volume, to be still further enlarged in the oven to at least twice the volume of the original dough. In the oven they do not touch each other, and the baking occupies about 15 minutes. To glaze the surface they are touched in the process of baking with a sponge dipped in milk, which, besides imparting to them a smooth surface, increases the brilliancy of the slightly reddish cinnamon color and adds to the grateful aroma of the crust. No peculiar form of oven is required, the only necessary point being that the receptacle shall be capable of maintaining a temperature of about 500 degs. Fah.

French Cookery.

Meats should be selected with a view to the methods of cooking to be adopted. The French never boil meats unless for the purpose of making soups. They regard boiled meats as comparatively worthless and never serve them unless in some prepared form, to restore flavor and lost nutrient principles. We forget in this country that to boil food, be it meat or be it vegetables, is to extract from it, first, its volatile aroma, then its essences or juices, its nutritive power; and these go out into the hot water which is stupidly thrown away. Boiling meat or vegetables in France is to make soup, and so saving are they that even the water in which beans and cauliflower have been boiled is always kept to serve as a basis for vegetable soup. Every liquid which has received the extracted flavor of a boiled substance is looked upon as precious, and is employed again in some form, so as not to waste the properties which it has acquired. The entire system of French cooking, both in form and practice, is to save the whole nutritive elements of every substance, to pass into the stomach, instead of allowing it to be poured down the sink spout or sending it to the pigs. The lesson taught us in this regard should be heeded. Butchers' bones, and those of fowls, which here go to the waste bucket or to the soap boiler, covered with fragments of meat and loaded internally with rich suet, are in France carefully sought for and employed in making soups. Nothing is wasted which can be used for human food. Soups are so common it may be said the nation lives on them. The average earnings of laborers in France do not exceed 30 cents a day, and yet from this pittance they continue to live comfortably. The average of health in the population is much higher than in most countries, and the average length of life is as high as 38 years.

Subscription and Advertising Rates:

ADVERTISING RATES.—1 week. 1 month. 3 months. 1 year.				
Per line.....	25	80	\$2.00	\$5.00
One-half inch.....	\$1.00	3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

Subscriptions payable in advance.—For one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by Registered letters or P. O. orders at our risk.

Prompt Subscriptions.

We wish to thank those subscribers who send in their renewals to the PRESS promptly as regularly as the year comes round. It saves us much expense in commissions for collections and renewals. May we not request more of our good patrons to do so!

THE ORIGINAL ARTICLES in this paper are mostly so in solid type, giving in our columns one-third more reading than is contained in ordinary loaded matter.

Our latest forms go to press on Thursday evening.

San Francisco:

Saturday Morning, April 22, 1876.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Industrial Depression; Ore Feeders; Explosions in Mines, 257. Deep Mining Shafts in Europe; Mining Machinery Improvements; Successful Frost Fighting; Reducing Our Iron Imports, 264. Gems and Precious Stones; Natural History of the Saal; Metallic Railway Cars; The Mechanics' Institute Improvements; A Simple Pumping Power, 265. Patents and Inventions, 268.

ILLUSTRATIONS.—Automatic Ore Feeder, 257. A Simple Pumping Power, 265.

CORRESPONDENCE.—A Winter Visit to Mammoth Cave, 258.

MECHANICAL PROGRESS.—Some English Metal Work for the Centennial; Twenty-Two Inch Plate; Immense Wire Ropes; Patents in the United States; The Telemeter; Cork Springs; Giffard's Cold Air Engine, 259.

SCIENTIFIC PROGRESS.—Measuring Earthquakes; Nitro-Glycerine Transportation; Preserving Plants with their Colors; Fascinations of Science—Straightening the Mississippi; New Specific Gravity Apparatus; A Quatern of Good Rules for the Student; New Electric Light, 259.

GENERAL NEWS.—General News Items and Miscellaneous Paragraphs, on 260 and other pages.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments; Meetings and Dividends; Review of the Stock Market for the Week, 260-1.

MINING SUMMARY from various counties in California, Nevada, Idaho, Oregon and Colorado, 261-2-3.

USEFUL INFORMATION.—How to Use Leather Belting; Back Varnish for Iron; To Make Putty; Straightening and Bending Pipes; Fraud in Graham Flour; Hardened Paper; Alcohol as a Food Preserver, 263.

GOOD HEALTH.—Candy; Dangers of the Shop; Perfect sleep, 263.

DOMESTIC ECONOMY.—How Vienna Bread is Made; French Cookery, 263.

MISCELLANEOUS ARTICLES.—Tin; A New Mine; The Mines of Arizona; The African Coast, 268. A New Source of Rubber; A New Fuel—Anthracite Coke; An Old Anvil; Diving in the Ocean for Fresh Water; A Rice Planter Mine; Rapid Increase of Narrow Gauge Railroads; Actylina Copper; American Hardware in England, 262. Tellurium—How to Make It; Curious and Interesting Facts; No Time to Read; Cheap Sewing Machines, 266. Important Land Decision; The New Homestead and Pre-emption Law of Congress; How to Get into the Centennial Exhibition; Women's Department at the Centennial, 268. Mining in Butte, 270.

NEW ADVERTISEMENTS.

Tulloch's Automatic Ore Feeder, F. Ogden, S. F.; Caution to the Public, R. L. S. Ball and R. M. Fryer, Grass Valley, Cal.; Wanted—A Superintendent, Hubb & Luckhardt, S. F.; Paul's Dry Process, A. B. Paul, S. F.; Quartz Mine and Mill for Sale, A. Grummet, Oregon Gulch, Cal.

THE OLD BAY STATE AT THE CENTENNIAL.—Massachusetts will make a novel, interesting and instructive exhibition at the Centennial, which will consist of a selection of models of the varied marine craft which has been employed in her waters since the first settlement of Plymouth colony. The collection will include some 50 or 60 models—all neatly and some most elaborately executed, and all perfect in type. The contributions are generally from the most noted ship owners and ship builders of the State, and represent every stage of progress in the art, from the Indian birch canoes and first fishing boats used on the coast, up to the most improved modern iron-clad. The paper boat in which Mr. Bishop made his famous trip from the Gulf of St. Lawrence to the Gulf of Mexico, will also have a place in the collection.

INTERESTING MINERALS.—Mr. S. S. Taylor, of Spanish Ranch, has sent us two mineral specimens for a name. We submitted both to Prof. H. G. Hanks, of the State University, for examination, who pronounces the greenish mineral to be a very beautiful variety of "idocrase," and valuable as a gem. The dark specimen is "psilomelane," an oxide of manganese, generally hygroscopic. This mineral is quite common near San Francisco, and is abundant at Red Rock.

Deep Mining Shafts in Europe.

Twenty years ago the deepest mining shafts in the world reached only about 2,000 feet below the surface. The very deepest, we believe, was a metalliferous mine in Hanover, which had been carried down to the depth of 2,290 feet. The deepest perpendicular shaft to-day is the Adalbert shaft in a silver-lead mine in Prizibram, in Bohemia, which in May last had reached a depth of 1,000 metres—3,280 feet. The attainment of that depth was made the occasion of three days' festival, and still further noticed by the striking off of a large number of commemorative silver medals, of the value of a florin each. There is no record of the beginning of work on this mine, although its written history goes back to 1527. Quite recently an elegant commemorative volume has also been written and printed, which an English paper before us says is "most interesting to those who have a taste for either the actualities or the antiquities of mining industry."

There are two other localities, however, where a greater depth has been reached than at the Adalbert shaft, but not in a perpendicular line. These are, first, the Rocksalt bore hole, near Spereberg, not far from Berlin, which a few years ago had been bored to a depth of 4,175 feet; and, secondly, the coal mine of Viviers Reums, in Belgium, where the miners, by shaft sinking, together with boring, have reached a total depth of 3,542 feet. Turning from these two mines, no shaft, in unbroken perpendicular line has, as yet, exceeded the depth of 3,280 feet. Taking each singly the deepest shafts in the world, at the present moment, group themselves according to the following order:

1. The already mentioned Adalbert shaft, 3,280 feet deep. As the top of this shaft is 1,732 feet above the sea level, the bottom is, of course, 1,548 feet below it.

2. Two shafts near Gilly, in Belgium, are sunk to the depth of 2,847 feet. At this depth they were both connected by a horizontal drift, from there an exploring shaft is sunk to a further depth of 666 feet, and from there again a trial bore, 49 feet in depth, is put down, so that the total depth reached is 3,542 feet. As they did not, in the bore hole, discover the sought-for coal seam, they have returned to the shaft at the 2,847-foot level.

3. The Eimgkerts shaft of the Lugauner coal mining company, Rhenania, Lugaun, in the kingdom of Saxony, is 2,653 feet deep.

4. The Sampson shaft of the Oberhartz lead and silver mining works, near St. Andreasberg, Hanover, has a depth of 2,437 feet, is at present the deepest shaft of Prussian mining.

5. The winding shaft of the Rosebridge colliery, near Wigan, Lancashire, England, has a depth of 2,458 feet. Coal is drawn from the "banging on" at the 2,418-foot level; the time of the cage running this distance being 55 seconds; the winding rope has, therefore, an average speed of 44 feet per second.

6. A shaft at the coal mines of St. Luke, near St. Chamont, in the Loire department, France, reaches 2,253 feet.

7. The shaft of the Dunkirk colliery, near Dukinfield, Lancashire, is 2,069 feet deep, but the mining is prosecuted to a further depth of 755 feet by shafts from the lower levels, making a total depth of the mine of 2,824 feet.

8. The deepest shaft of the collieries near Ronchamp, in France, is 1,891 feet. A similar depth has been reached by the argentiferous mine near Kongsberg, in Norway. The mines belonging to the Roros copper works, in Norway, have worked to the depth of from 2,540 to 4,270 feet.

9. The Amalia shaft in the mine works near Schemnitz, in Hungary, 1,782 feet.

10. The No. 1 Camphausen shaft, near Fishbach, in the department of the Saarbrück collieries, has now reached the depth of 1,650 feet and may possibly become the deepest shaft in Prussian coal mining.

Although the depths to which the shafts enumerated have penetrated into the interior of the earth in the art and practice of mining may appear mighty, and may be an expressive witness of the great progress made in mining pursuits; yet, on the other hand, the above results may be considered insignificantly small when we compare them with the extent of the earth's crust and the diameter of the earth.

The deepest bore hole in the world is the artesian spring at Potsdam, in Missouri, which reaches a depth of 5,500 feet.

THE MISSISSIPPI'S MOUTH.—Capt. Eads has made application for the first payment on his work at the mouth of the Mississippi, which was to become due when there were 20 feet of water on the bar. This depth he believes will be reached in a few days, and the full depth of 30 feet will be secured by the latter part of next summer. It may be remarked that there still remain some disbelievers in the practical value of this deepening of the mouth of the Mississippi. It is held by such that as the channel deepens the mud which is thus removed will only be carried a little farther out, and be again deposited so near the jetty as to form a mud bar, out to which the work will have to be carried, and so on *ad infinitum*. But some people never will be convinced of anything.

Mining Machinery Improvements.

Experience has shown that working on narrow margins of profit is to be the condition of the future. Economy of production is of more importance than the first cost of the raw material—hence the increased attention that is being paid to the introduction of improved machinery and other appliances. Competition is constantly decreasing the already narrow profits which have for some time existed, and the fullest employment of labor-saving machinery is the only road to profitable production. We find this condition of things existing in every department of industry, and he who ignores it does so at his peril. Our Patent Office reports and industrial newspapers are filled with illustrations of new and improved machinery, all having in view the saving of hand labor and the cheapening of production.

The great industry of mining, in which our own State is so much interested, is no exception to the rule, but on the contrary shares largely in the benefits derived from such improvements. The improved automatic ore feeder illustrated in another column is a case in point. Improved blasting powders, which largely reduce the labor attendant upon drilling, and improved rock drills, have greatly reduced the cost of mining and rendered many mines valuable which a few years ago could not be worked to a profit. Perhaps no department connected with mining has been so largely improved within the last 10 or 15 years as that of drilling and blasting. Machine drills are now manufactured in large numbers, both in America and Europe, and sent to all parts of the world.

In coal mining machines have long been in use that will cut a thin channel or groove in the coal, so that it may be removed in larger quantities and with less waste in coal, time and labor than can be done with the pick or blact, and by which great economy has been introduced in that important branch of mining. And now we hear that that principle has been adapted to vertical as well as horizontal work, and successfully applied to the sinking of shafts and wells, either in picking earth or solid rock. This work is accomplished in the following manner:

A circular track, somewhat less in diameter than the intended shaft, is laid, and on this the cutting machine travels, and cuts a ring about 1½ inches wide and 20° deep, in the soil, rock, or other material. A hole sunk by a drill in the center is then charged, and on removing the outer to a safe distance a blast is fired in the middle of the core. The blast shatters the core but does not injure the sides of the annular cut. In hard rock the annular cut leaves a good surface for the interior of the shaft, and in softer rocks or soil, timber or masonry is readily added.

MINING THE GREAT CIVILIZER.—The London Mining World discourses on the effects of mining on civilization at considerable length, and very legitimately concludes as follows: "It is not too much to say that all the civilization of which we boast may be traced to the application of the metals and the use of coal. Wherever nations have learned to mine and work metals, they have become powerful and rich, subduing their neighbors either by force of arms or by greater industrial activity, and in either case acquiring their wealth. In the earlier stages those who possessed the metals made an easy prey of their rivals, and in the present day, nations mining their coals and metals do in a better and more elevated sense outstrip their competitors and become the masters of the world. All history teaches that those nations which learned to mine and work metals became wealthy, powerful and civilized, whilst those which had no mining industries or no metallic manufactures have remained in a state of barbarism, and that such at the present day is the distinguishing feature of savages. Mining industry is indeed the foundation of all civilization, and the chief basis on which all industries must rest, as well as being at the same time the principal element of progress. Without it the working class could gain little beyond the mere necessities, and as we have often shown that coal and iron are the first requisites of national prosperity, so it is to mining that we must refer the advancement of the present age."

GOLD IN INDIA.—The Madras newspapers have recently given some accounts of the Colar gold fields, in Mysore, and of the operations which have just been commenced there by the Ooregam gold mining company. The auriferous quartz reefs are said to extend for a distance of nearly 20 miles, and are only about 12 miles from a station on the Madras railway. The company has already sunk one main and two auxiliary shafts, the former of which is expected to cut the reef at about 60 feet. The works have been so recently begun that it is not yet possible to form any accurate idea as to the probable results, but it seems to be thought that the field is one of great richness; moreover, it has a history which is said to go as far back as the year 1293, when Allagene, a general in the service of the Emperor of Delhi, returned from an invasion of Mysore, bringing with him a large amount of gold. Hyder Ali and Tippoo Sahib would also appear to have worked the mines. Should it turn out that the reefs can be profitably worked, the facts that they are situated at an elevation of 3,800 feet, and that the climate is good, will doubtless tempt many Europeans to try their fortunes there.

Successful Frost Fighting.

Last week we noted the French method of guarding against the fruit destroying frosts of springtime, and mentioned several cases of the application of the practice in this State. We have now information of success with the frost fighting fires in the foothills. The Amador Ledger says: "Wm. Avala, who owns perhaps the largest orchard around here, has this year adopted the plan of keeping fires burning on the windward side, the wind carrying the smoke and heated air over the trees, and preventing the formation of frost. On Monday morning we were favored with a nipping frost, which we are informed has inflicted serious damage upon the fruit. Avala that morning had 120 fires burning on his garden of 50 acres, and he reports his fruit uninjured. The cost of the experiment is inconsiderable. It is rarely necessary to light up more than three or four times in a season, and the cuttings from the vines and trees are about sufficient for the purpose. He calculates that this simple precautionary measure will save him something like \$1,000."

The importance of this safeguard against loss by frost is vital to our fruit interest in many parts of the State. The cost of saving the fruit cannot be compared with loss which is occasioned when it is ruined. It is of special value that the remedy is so cheap and so easily applied. We trust that our fruit-growing readers in exposed situations will save up their rubbish during the coming season and be prepared to give the frost a warm reception next spring. There is money in saving a crop just at a time when negligent husbandmen are cropless.

Reducing Our Iron Imports.

The great and rapid reduction which is being effected in our imports, and the consequent decrease in the necessity of specie exports to meet foreign balances, must soon exert a most favorable influence upon the general industrial interests of the country, and will, eventually, once more bring about the era of "good times." So marked and important is that change in our foreign trade that such a result cannot be much longer delayed. But in no department of industry is this change being more rapidly developed than in the iron trade.

During the first two months of 1874, our imports of railway iron were 16,978 tons; during the same period in 1875, they were 4,981 tons, and during the first two months of the present year this import was just 54 tons! In 1864 we imported steel rails at a cost of \$150 per ton. To-day we are making those same rails at a cost of only \$61 to the ton. No wonder the British iron men are despondent. They have lost their best customer, and even the miscellaneous iron manufacturers of Sheffield confess that they have next to no orders on their books from the United States. We have fairly turned our back upon Johnny Bull, the natural outcome of which will be increased work for our own mechanics and better times for all.

NEW SUBSTITUTE FOR GOLD.—The following is a new metallic alloy which is now very extensively used in France as a substitute for gold: Pure copper, 100 parts; zinc, or preferably tin, 17 parts; magnesia, 6 parts; sal-ammoniac, 3.6 parts; quicklime, 1.8 parts; tartar of commerce, 9 parts; are mixed as follows: The copper is first melted, then magnesia, sal-ammoniac, lime and tartar are added separately and by degrees, in form of powder. The whole is next stirred briskly for about half-an-hour so as to mix thoroughly, after which the zinc is added in small grains by throwing it on the surface and stirring it till it is entirely fused. On this being done the crucible is then covered and the fusion maintained for about 35 minutes, after which the surface is skimmed and the alloy is ready for casting. This alloy has a fine grain, is malleable, and takes a splendid polish. It does not corrode readily, and for many purposes is an excellent substitute for gold.

THE PAYING OUT OF SILVER COIN for the redemption of fractional currency has been commenced. Redemptions are made at the office of the Treasurer of the United States at Washington, Assistant Treasurers at Boston, New York, Philadelphia, St. Louis, Charleston, New Orleans, Cincinnati, Chicago, San Francisco and Baltimore, and at the United States depositories at Buffalo and Pittsburgh. Fractional currency sent by express or otherwise to the offices named, for redemption, should be accompanied by a letter of advice, stating fully the address of the sender and how remittance in payment therefor is desired; and if by Treasurer's check, the office at which the check should be made payable. The Government will not pay express charges on silver issued or fractional currency presented for redemption.

Those merchants and other business men who want to sail smoothly should use a little printer's ink. It is the best specific we know of, and our columns constantly show that the best and shrewdest men use this popular remedy to "keep things moving." A few dollars paid out in judicious advertising has in a thousand instances enabled business men to ride over a storm and reach a safe harbor. To sit in silence or groan over events, or resolve to do nothing is palpable evidence of folly or weakness, or both.—Ex.

Gems and Precious Stones.

[Written for the Press by HENRY G. HANES.]

(Continued from last week.)

I have already stated that the diamond generally crystallizes in octahedrons or dodecahedrons, rarely in cubes. To show that these forms are based on the same system I would suggest to the reader that he make a few simple experiments as an illustration.

On consulting works on crystallography it will be found stated that the cubic system is also called the isometric system, and that there are three axes, rectangular and equal.

To understand this take a raw potato and cut out a cube, as shown in the engraving, D. In

the center of each face make a point, and from the top face run a pin down through the cube; let this be called the vertical axis. Now if two other pins are pushed through the other faces to represent axes, it will be seen that there are three and that they are of equal length (if the cube is perfect). It will also be seen that all the angles are right angles. Now draw a line parallel to the table through the four centers of the side faces of the cube and cut from the center of the upper face to these lines; then reverse the model and treat the lower half in the same manner. A perfect octahedron will be produced, represented by the engraving E. I might show that the dodecahedron is also a modification of the cube, but it will not be necessary.

The cutting of the diamond is based on this crystalline form. There are three modes of cutting the diamond, as shown in the engraving.

The shape of the rough stone and the taste or want of taste of the owner determines which style shall be adopted. The rose is shown in A, the brilliant in B, and the cabochon in C.

The art of cutting diamonds by their own powder originated with Louis Berghem, of Bruges, in the year 1476. At first the style was a flat table with facets on the edges. The brilliant was invented during the reign of Louis XII. Cardinal Mazarin is said to have been the first who had diamonds cut in that form. That the reader may know exactly what a brilliant is, I will describe the principles upon which they are made.

Let us return to the octahedron standing as it was cut from the cube; suppose the vertical axis to be divided into 18 parallel lines, as shown in the engraving. The central portion of the crystal, or the horizontal line where the two pyramids join, is called the "girdle." The upper portion of the octahedron is cut off at the 5th line, leaving the flat surface A, which is the "table;" one-eighth of the bottom is then cut off, leaving a small face called the "culet." The remainder of the crystal is a perfect square brilliant. The edges and corners are then cut and polished and the finished brilliant, B, is the result. Any deviation from this will make a badly shaped stone. The value of a gem is also based on the same rule, for a diamond is worth only what a perfect brilliant would be which can be cut from it. Sometimes to make a diamond appear larger the angle of the crystal is made greater than 90 degrees. Such a stone, wanting in depth, is deficient in brilliancy, although appearing larger than a perfectly proportioned stone. Such diamonds are called "spread brilliants." In other cases for certain reasons the angle is less than 90 degrees. The table is then smaller than it should be, and is unsatisfactory to the educated eye.

David Jeffries, who wrote a work on diamonds and pearls, published in London in 1750, and from whose book I have taken the above rule for cutting the true brilliant, gives drawings of brilliants from one carat to 100 carats, increasing by eighth of a carat. Under each model

is a small bar showing the proper depth from the table to culet, and below the bar the size of the culet. The table is used as follows: Suppose the reader has a diamond which weighs four and one-eighth carats, and wishes to ascertain if it has been properly cut: With a pair of small calipers he takes the width of his diamond and compares it with the model of a brilliant of the same weight in the table. Then with the calipers he takes the thickness of the stone, from table to culet, and compares it with the bar below the model. Lastly, he measures the size of the culet; if the diamond is badly cut the defect will be seen at once. These tables have been copied ever since, and may be found in any work on diamonds and precious stones.

The engraving at the bottom of the other column shows a few of these models.

Metallic Railway Cars.

The question of substituting metal instead of wood in the construction of railway cars is not a new idea. We have several times alluded to

METHOD OF CUTTING THE BRILLIANT.

to it in our columns. Metallic cars have been built both in this country and in Europe; but, as heretofore constructed, their advantages, when compared to wooden ones, have been considered of so doubtful a character, that they have been generally condemned, for being too heavy, hot and cold, too noisy and expensive, and incapable of being readily repaired.

Profiting by the experience of the past, a company at Providence, R. I., as we understand, has lately undertaken the practical solution of the problem of metallic cars, both for

We understand that one of these cars will arrive soon in this city with a load, all the way through from New York, when it will be subjected to the free inspection of our railroad men and mechanics on the Pacific coast, and will probably be put to active use to further test its qualities. Several of these cars have lately been placed upon one of the roads out of Worcester, Mass., where we understand they are doing good and satisfactory service. We shall probably have occasion to make further references to these metallic cars after the opportunity has been offered for personal inspection, as promised above.

REMARKABLE DISAPPEARANCE OF LAKES.—Reports from Lowndes county, Georgia, speak of the recent sudden disappearance of several lakes in that county. There are a large number of lakes there, from 10 to 500 and 1,000 acres in area. In September last one dried up or ran off, and left many barrels of fish in holes of water about upon the bottom of the lake. In January another, about five miles from this, did the same thing, and subsequently Grassy pond, a lake covering

HORSE-POWER FOR OPERATING PUMPS.

about 500 acres, between the two above mentioned, left its millions of fishes out of water. The waters of this lake sank gradually out of sight, during a period of three weeks. As soon as the waters were low enough for the use of scoop nets, hundreds of people gathered about and gathered the fish by cart loads; and when it had all disappeared millions were left dead upon the ground, from which they were carted off for manure. The waters, at latest accounts, were again returning into the beds of the lakes. "What's the matter?" is the question universally asked, and as yet without an answer, as the like was never known there

before, and the season precludes the possibility of attributing the phenomena to ordinary evaporation.

PACIFIC COAST ORES FOR THE CENTENNIAL.—Mr. John Hatch, an old Californian, left on the overland train for Thursday for the Centennial exposition, with five tons of specimens of the mineral deposits of the Pacific coast and Mexico, collected by him during 12 years of arduous labor. Each specimen is labeled with its appropriate scientific name and the locality from which it has been taken. This collection will be a feature of the exposition, as it will illustrate the richness of the mineral resources of this coast. The collection is valued at about \$50,000.

STILL ANOTHER ASTEROID.—A telegraphic dispatch from Ann Arbor, Michigan, announced that Prof. Watson discovered on the night of the 16th instant, in the constellation Virgo, a planet hitherto unknown, continued observation of which was interrupted by clouds. The next night he observed it satisfactorily. It shines like a star of the 11th magnitude. Its position is, right ascension, 13 hours 29 minutes; declination, 11 degrees 47 minutes south. This is undoubtedly another asteroid.

The Mechanics' Institute Improvements.

The work of improving the library building of the Mechanics' Institute on Post street is now nearly completed. The more noticeable improvements are in the library rooms, which had become inadequate to the demands made upon them, but which will now accommodate any accessions they may receive for some time. The reading room, which was before situated on the same floor with the library, has been removed to the upper floor, next to the chess room, while the quarters it formerly occupied have been connected with the main library room by large folding doors. Shelves with a capacity of more than 5,000 volumes have been built about this room, and upon them are placed a complete edition of the English patent office report, consisting of about 3,000 volumes. These contain a complete history of English invention, from the year 1617, when the British patent office was established, until the present day. It is difficult to estimate in dollars and cents the value of this addition to the library. Only two other libraries in the United States enjoy a similar possession, and the trustees of the Mechanics' Institute are to be congratulated upon their success in obtaining for the use of its members a gift which the British government is usually so chary in bestowing. It is probable that this will be the only work of the kind ever found upon the Pacific coast, for it is nearly out of print, and only personal influence with high officials is able to procure it. These books as now arranged upon the shelves present a fine appearance. They are of uniform size, bound in red half morocco, and with gilt lettering, and, displayed as they are in a well lighted room, give a peculiarly bright appearance to the apartment, and even seem to make the dry details and specifications of the patent poetic. Each volume is furnished with careful drawings of the inventions, with the exception of those since the year 1871, which comprise only the printed descriptions, the plates being contained in larger volumes, which stand upon adjoining shelves for ready reference.

It may be interesting to note that the first recorded English invention was for a plan of engraving and printing maps, granted to Aaron Rathbone and Roger Burges, who received their papers from James I. It is the intention of the trustees to employ this room mainly for the accommodation of Patent Office reports, and those of the United States already upon the shelves. This room, like the one which has long been in use upon the other side of the hall and staircase, is to be used for reference solely, and none of the books it contains are to be taken from it. By the new arrangement the door which formerly connected this room with the hall has been closed up. The ladies' entrance, which was found to be unnecessary, has also been done away with, thus giving a greater width to the room and to the store directly under it on the ground floor. Much advantage has also been gained by removing the reading room to the upper story. By it a greater degree of quiet has been secured, and by a sky-light in the roof and an improved arrangement of gas burners, the eyes of readers, which were sometimes tried in the lower room, are much favored.

On the lower floor the improvement is even more marked. Corinthian hall has been done away with, the floor has been raised several feet, and the three stores remodeled into two and extended back to the end of the building, nearly doubling their capacity and affording them perfect light and ventilation by the windows in the rear. The basement has also been enlarged for the more complete storage of supplies. In short, the building and all its appointments have suffered a thorough overhauling and with very satisfactory results. We copy the above substantially from the *Morning Call*.

A Simple Pumping Power.

We present our readers herewith the illustration of a novel horse power for operating pumps, the invention of Mr. Frank A. Hill, the well known and gentlemanly superintendent of the agricultural machine works and depot at San Leandro, in this State. Mr. Hill is the inventor of the Enreka gang plow, which recently defeated all antagonists at the plowing match at Rio Vista, and he seems determined to supply our farmers with economic, simple and effective machinery for doing all kinds of farm work. And *en passant* we would say that Mr. Hill has secured United States letters patent on the above named inventions—and a great many more—through the MINING AND SCIENTIFIC PRESS Patent Agency. The horse power, it will be seen, consists of a centrally pivoted walking beam, one end of which is connected with the pump rod by a pitman, while the opposite end is connected with a crank wheel by a similar pitman. This crank wheel is secured upon the end of a horizontal shaft, which is supported by a suitable standard near the wheel. The outer end of this shaft has a large traction wheel mounted on it, and the horse is hitched to the shaft near the traction wheel. As the horse travels around in a circular track, the traction wheel rotates and the motion is transmitted through the crank wheel, oscillating beam and pitman to the pump rod. This arrangement is extremely cheap and simple, and cannot help but be effective.

Parties desiring to learn further particulars in relation to this device, can address F. A. Hill, San Leandro, Cal.

Tellurium—How to Make Tests.

A correspondent of the *Lassen Farmer* furnishes that journal with the following information on the above named subject: "In looking over your issue of March 4th, I see a request for some information on the metal tellurium. If you have not already been supplied from some more able source, I send you the following for publication: Tellurium is a metal of a tin-white color, about as hard as rock salt or gypsum, having a specific gravity of 6.1. It is most generally found to contain some iron and gold. It is very rarely found in small columnar crystals; usually it appears as a very fine-grained impregnation. It is easily melted before a blow pipe, when it colors the flame a bluish green, and in evaporating leaves a grayish white sublimate, red edged on the charcoal. It is soluble in nitric acid. Heated in concentrated sulphuric acid it imparts a red color to the acid, which, however, disappears again on greater heating. Should the acid be diluted during the time the red color is present, a grayish black precipitate is produced. The metal is also found in telluric-silver, a mineral of a lead or steel gray color, somewhat ductile, but of a higher specific gravity than the former, easily melted with a blow-pipe to a globule, throwing off a sublimate as above. Another telluric ore is known as sylvanite; this is softer than either of the former, of a steel-gray or silver-white color, and is composed of tellurium, gold and silver. This mineral, when treated with a blow-pipe, on charcoal, gives a dark gray globule and a white sublimate, which globule, on the addition of a little soda, by further blowing, results in a light yellow globule of argentiferous gold, or gold and silver. In nitric acid sylvanite dissolves, with the exception of the gold. In aqua fortis this mineral dissolves and throws down a precipitate of chloride of silver, and in concentrated sulphuric acid, it acts the same as tellurium. Tellurium is likewise found in connection with lead, and bismuth, and antimony.

Curious and Interesting Facts.

A VALUABLE manuscript has been discovered in the Azores. It refers to the colonization, in the year 1500, of the northern part of America by emigrants from Oporto, Aveiro and the island of Terceira. It was written by Francisco de Souza, in 1570, and was lost during the great earthquake of Lisbon, in 1755. This important document is about to be published, and, it is thought, will throw a great light on the disputed question of the early discovery of America.

THE latest contribution to the dispute about spontaneous generation is a letter from Prof. Tyndall to the *London Times*, in reply to Bastian, wherein the former says: "Many of my infusions, prepared with the most scrupulous adherence to his own prescription, have been exposed for weeks to temperatures varying from 80 to 90 degs. Fah., and have remained perfectly sterile throughout. A temperature 20 degs. lower than these rapidly develops putrefaction in the common air."

AN Eastern paper gives an account of an accident that happened to a man who was at work near a shaft that revolved at a rate between 100 and 150 times per minute, and who, being caught, was whirled around and then thrown off unharmed, but with only his shoes and stockings left on. Two similar accidents happened in this vicinity at different establishments; in neither instance were the victims hurt, but only their shoes and stockings left on.

IF a ladle of molten (pig) metal be poured in steady stream on to a chilled cast iron body it will cut a hole in it more rapidly than if poured on a cast iron body that has not been chilled.

NO TIME TO READ.—We have often encountered many who profess to believe they have no time to read. Now we think of it, there have always been men of such characters, the points of which are easily summed up.

Nine times out of ten, they are men who have not found time to confer any substantial advantage either upon their families or themselves.

They frequently spend whole days in gossiping, tipping and swapping horses, but they have no time to read.

They sometimes lose a day in asking advice of their neighbors; sometimes a day in picking up news, the prices current, and the exchange, but these men never "have time to read."

Such men generally have uneducated children, unimproved farms, and unhappy firesides. They have no energy, no spirit of improvement, no love of knowledge; they live "unknowing and unknown," and often die unwept and unregretted.—*Ex.*

CHEAP SEWING MACHINES.—It is said that the refusal of Congress to extend the patent for the "four motion feed" in sewing machines, owned by the Wheeler & Wilson and Willcox & Gibbs companies, which required all other manufacturers to pay a heavy royalty for the use of it, promises to reduce the price of machines before long about 30 per cent.

W. F. & JNO. BARNES, Manufacturers of Barnes' Patent Foot-Power Machinery, Scroll-Saws, Circular Saws, Lathes, etc. The only Foot-Power Machine without crank or dead centers. \$1,500 to \$2,000 per year made using these Machines. Send for Illustrated Catalogue. Rockford, Winnebago county, Ill.

OF INTEREST TO MINING COMPANIES.

A Mining and Civil Engineer, of long experience, collected in Europe and America, well acquainted with correct management of mines and mills, practised in projecting and constructing mining and milling machinery, and especially machinery for mechanical ore concentration, is open for re-engagement, and would prefer the task of constructing works for mechanical concentration of low grade ores on a well developed mine, or of remodeling ineffective works in the ore milling line for successful operation. Apply to Messrs. DEWEY & CO., of this office, for reference.

F. MANSELL & CO., SIGN PAINTERS,

423 PINE STREET,

(Between Montgomery and Kearny.)

Persons engaged in the following business can have their Signs Painted at contract prices, for goods or articles in which they trade, viz:

DEWEY & CO.

American & Foreign Patent Agents.

OFFICE, 224 SANBOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Victoria, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Grenada, Chili, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule prices for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more directly judge of the patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing them to the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents, or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 224 Sansome St., S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and Retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY CUIDO KUSTEL, MINING ENGINEER AND METALLURGIST.

Ronsting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quick Silver, 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his speciality.

Price \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE REDUCED TO \$5.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy.

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E.,

California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE, bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for \$5c. extra, at the Mining and Scientific Press Office, by

DEWEY & CO.

WILLIAM MARTIN—Alameda county.
DR. J. T. JOHNSON—California and Nevada.

AMPO, SAN DIEGO CO., CAL., July 3d, 1874.
MESSRS. DEWEY & CO.—Gentlemen: To-day I received the patent and other papers of my animal trap, that you so successfully worked through the patent office for me, for which please accept my best wishes. The chances are that I will have another application for you to make for me before long. I am well satisfied with your manner of doing business, and I think inventors of this coast stand in their own light when they do not put their business into your hands.

I remain yours truly, A. M. GASS.

SACRAMENTO, May 29th, 1875.

MESSRS. DEWEY & CO.—Gentlemen: The patent came duly to hand yesterday, by express. Please accept thanks for your promptness in obtaining the same. Very respectfully, DUNCAN BEAUMONT.

IRON PIPE.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, at the cheapest appropriate medium for the same.

California Acclimatizing Society—Location

of principal place of business, San Francisco, Cal. Notice is hereby given, that at a meeting of the Board of Directors, held on the seventh day of April, 1876, an assessment (No. 7) of fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately, in United States gold coin, to the Secretary, at the office of the company, room 37, Nevada block, No. 309 Montgomery street, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the seventeenth day of May, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the seventh day of June, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, W. W. TRAYLOR, Secretary, pro tem.

Office, room 37, Nevada block, No. 309 Montgomery street, San Francisco, Cal.

The California Watch Company—Location

of principal place of business, No. 120 Sutter street, San Francisco, Cal. Notice.—There are delinquent upon the following described stock, on account of assessment levied on the eighth day of March, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't.
M Godley, trustee.....	1	3,000	\$15,000 00
A Rammelsberg, trustee..	2	200	1,000 00
A Rammelsberg, trustee..	3	100	500 00
T M Antisell.....	4	10	50 00
A Rammelsberg, trustee..	5	1,120	5,600 00
Paul Gordon.....	33	50	250 00

And in accordance with law, and an order of the Board of Directors made on the eighth day of March, 1876, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the company, on the first day of May, 1876, at the hour of twelve o'clock, p. m., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

H. T. GRAYES, Secretary.

Office, No. 120 Sutter street, room 10, San Francisco, Cal.

Eureka Stone Manufacturing Company—

Location of principal place of business, city and county of San Francisco, State of California. Notice is hereby given that at a meeting of the Board of Directors, held on the eighteenth day of March, 1876, an assessment (No. 3) of fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 857 Market street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fourth day of April, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before will be sold on the eighth day of May, 1876, to pay the delinquent assessment together with costs of advertising and expenses of sale.

P. D. MOWELL, Secretary.

Office, No. 567 Market street, San Francisco, Cal.

Klamath Quartz Mining Company—Location

of principal place of business, San Francisco, Cal. Location of works, Liberty township, Siskiyou county, Cal. Notice.—There are delinquent upon the following described stock, on account of assessment levied on the second day of March, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
E A Richardson, trustee....	44	500	\$1500 00

And in accordance with law, and an order of the

Board of Directors, made on the second day of March, 1876, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the Company, room 8, No. 315 California street, San Francisco, Cal., on Tuesday, the second day of May, 1876, at the hour of one o'clock, p. m., of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale. J. F. NESMITH, Secretary.

Office, room 6, 315 California street, San Francisco, Cal.

The Golden Sun Gold Mining Company.

Location of principal place of business, San Francisco, Cal. Location of works, Forks of Butte Mining District, Butte county, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1), levied on the first day of March, 1876, the several amounts set opposite the names of the respective shareholders, as follows:

And in accordance with law, and an order of the Board of Directors, made on the first day of March, 1876, so many shares of each parcel of said stock as may be necessary, will be sold at public auction on the 24th day of April, 1876, at the hour of two o'clock, p. m., at the office of the company, 702 Market street, room 2, San Francisco, Cal., to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale. J. S. PENTECOST, Secretary.

Office, 702 Market street, San Francisco, Cal.

Josephine Gravel Mining Company—

Location of principal place of business, San Francisco, California.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the twenty-third day of February, 1876, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Barth J. F. Trustee.....	10	1500	\$150 00
Boyd, John F. Trustee.....	14	500	50 00
Dow, C. C.....	6	1000	100 00
Mitchell, J. C.....	9	4000	400 00

And in accordance with law, and an order of the Board of Directors, made on the 23d day of February, 1876, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the office of the company, room 2, No. 535 California street, San Francisco, on the tenth day of April, 1876, at the hour of one o'clock p. m., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

WM. SMALL, Secretary.

Office, Room 2, No. 535 California Street, San Francisco, Cal.

POSTPONEMENT.—By order of the Board of Directors of the Josephine Gravel Mining Company the above sale is hereby postponed until Monday, the twenty-fourth day of April, 1876, at the same hour and place as aforesaid.

WM. SMALL, Secretary.

San Francisco, April 6th, 1876.

Lady Franklin Gold and Silver Mining

Company. Principal place of business, City and County of San Francisco, State of California. Location of works, Silver Mountain Mining District, Alpine County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the third day of April, 1876, an assessment of fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at his office, 507 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1876, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the fifth day of June, 1876, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

F. E. LUTY, Secretary.</

Mining in Butte.

The *Mercury* of April 7th says: Within the past five years the attention of capitalists has been turned to this county, with a view of developing the many rich placer mines that are everywhere throughout the foothills to be found. For years these rich placers were known. In some instances the ground was taken up, and after a time the owners disappeared and were not heard of for years, and only returned when they had succeeded in inducing capital to take hold with them. One case has just come under our notice. We refer to James L. Pond, who some 20 years ago was a resident of this town, doing business here. Then it was almost a daily occurrence for parties to come in from Magalia, loaded down with belts filled with lumps of gold. Many a one looked to this field as the richest to be found in this part of the State. Let the miner burrow anywhere into the hill-sides, and he found gold. At last mining almost ceased, not because the gold had all been taken out, but because it was so difficult to get water to the claims. Each miner left with the impression that in the future he would get rich, return and open here a mine that would astonish the world. Among those that have returned to develop and open up these mines, is the gentleman we have named. He brings with him one of the best surveyors that can be had, and has set him at work making the preliminary survey for a water ditch that will carry some 3,000 inches. He will soon have at work 150 men, and intends to have the whole completed by the first of July. A large and wealthy company has been formed in London, called the Isabinda gold company, limited, of which Mr. Pond is the superintendent. This same ground was being prepared last year, and some 50 men engaged for a long time in getting it into shape. Now it passes into other hands, and the working force is doubled with every prospect, as we said before, of being ready to turn the water on by the first day of July. Old residents of this county will recollect the rich diggings near Dogtown, now called Magalia. This is the claim referred to. It is the one that was purchased a short time ago by Mr. Pond and a Mr. Barry, of London, for \$200,000.

A SCHOOL OF SHEPHERDS has been established at Ramboulet, France, where young men over 15 are instructed in the science of sheep husbandry. The course is for two years.

SEWING MACHINES.—We have a first-class machine we wish to dispose of on favorable terms. Apply at this office.

WIRE ROPE

For Mining, Shipping, and General Purposes.

All kinds and sizes on hand, or made to order; guaranteed of unsurpassed quality, and manufactured of any length. FLAT ROPES, ROUND ROPES and TAPER ROPES, of IRON OR STEEL.

Patent Endless Wire Ropeway

(WIRE TRAMWAY)

FOR THE RAPID AND ECONOMICAL TRANSPORTATION OF ORES AND OTHER MATERIAL OVER MOUNTAINOUS AND DIFFICULT ROADS.

This system has been in use for over three years and given thorough satisfaction.

DRILLING MACHINES.

PORTABLE DRILLS. Driven by power in any direction, self-feed and convenient adjustment.

RADIAL DRILLS. Self-feed—large adjustable box table—separate base plate, every convenience.

VERTICAL DRILLS. Self-feeding—of new and improved designs.

MULTIPLE DRILLS. For boiler work, etc., 2 to 20 spindles, fed and returned by power or hand, together or separately.

HORIZONTAL BORING AND DRILLING MACHINES. For large pieces—with boring head, adjustable, vertically and horizontally.

SPECIAL DRILLS. For special work. Gun Blank Drills, Coal Drills, &c., built to order.

G. W. & C. A. LANE, Exeter, N. H., write, Dec. 13:

"We started the heavy 20-inch Corn Mill last Friday you sent to Baldwin & Tabor, Manchester, N. H. We ran it most all day, and ground 60 bushels corn per hour. The mill you sent us at Haverhill, Mass., for A. S. Hook, is doing wonderfully. It is grinding on an average 2,500 lbs. good meal per hour, and has ground 2,800 lbs. in an hour. It is driven by an engine with a 9-in. cylinder, and takes the place of a 30-in. mill of another kind that, when doing its best and loading the engine with all it could carry, only ground 1,500 lbs. per hour. If there is a mill built that can beat that we would be pleased to see it brought out."
